Site Characteristics.

	Site Name	**FGNK3**	
Discharge (cfs)	**1360 (1160-1560)**	Width (ft)	**83.1 (81.3-85.0)**
Slope	**0.0026**	Cross-sectional Area (ft^2)	**277 (248-303)**
D_{50}	**45**	D_{84}	**102**
Lat/Long Location	**N59.84681 W155.67949**	Drainage Area (mi^2)	**104**
	% Willow	**80**	
	% Grass	**15**	
	% Tree	**5**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections covering around 540 feet of stream. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Overwidened due to the entrance of a backwater channel along the left bank, Section 1 required the addition of an ineffective flow boundary to account for the lack of conveyance during high flows. Sections 4 and 5 characterize the riffle which serves as the reference reach and the pebble count was taken along Section 5. Obvious lag deposits were noted on site. A broad pebble count distribution is a further indication of the presence of lag. However, the pebble count was not modified because the degree to which lag was captured in the pebble count was not apparent. Aerial photo analysis suggests that this reach may be affected by ice, specific evidence is the presence of a cutoff bend downstream along with a uniquely straight stretch of channel.

For a Shields number of 0.026, the D_{50} begins to move through the upper cross-sections (6 through 4) by 1160 cfs. For a Shields number of 0.017, the D_{84} moves at 1310 cfs on Section 4 but appears to be immobile on Sections 6 and 5. However, for the ranges of flows an average particle size of 84 mm (range of 74-95 mm) will move on Sections 6 and 5. This particle size represents the sediment distribution found just downstream at FGNK1 and FGNK2 (D_{84} of 85 and 73 respectively). Geometrically, the range of flows, 1160-1560 cfs, matches the top of the gravel bar and right bank inflection point along the edge of the pool fairly well (Sections 2 and 3), with 1360 cfs hitting the crest of the gravel bar on Section 2. The higher end of the range matches the left bank inflection point on Section 6.

The reference reach sections (Sections 4 and 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGNK3

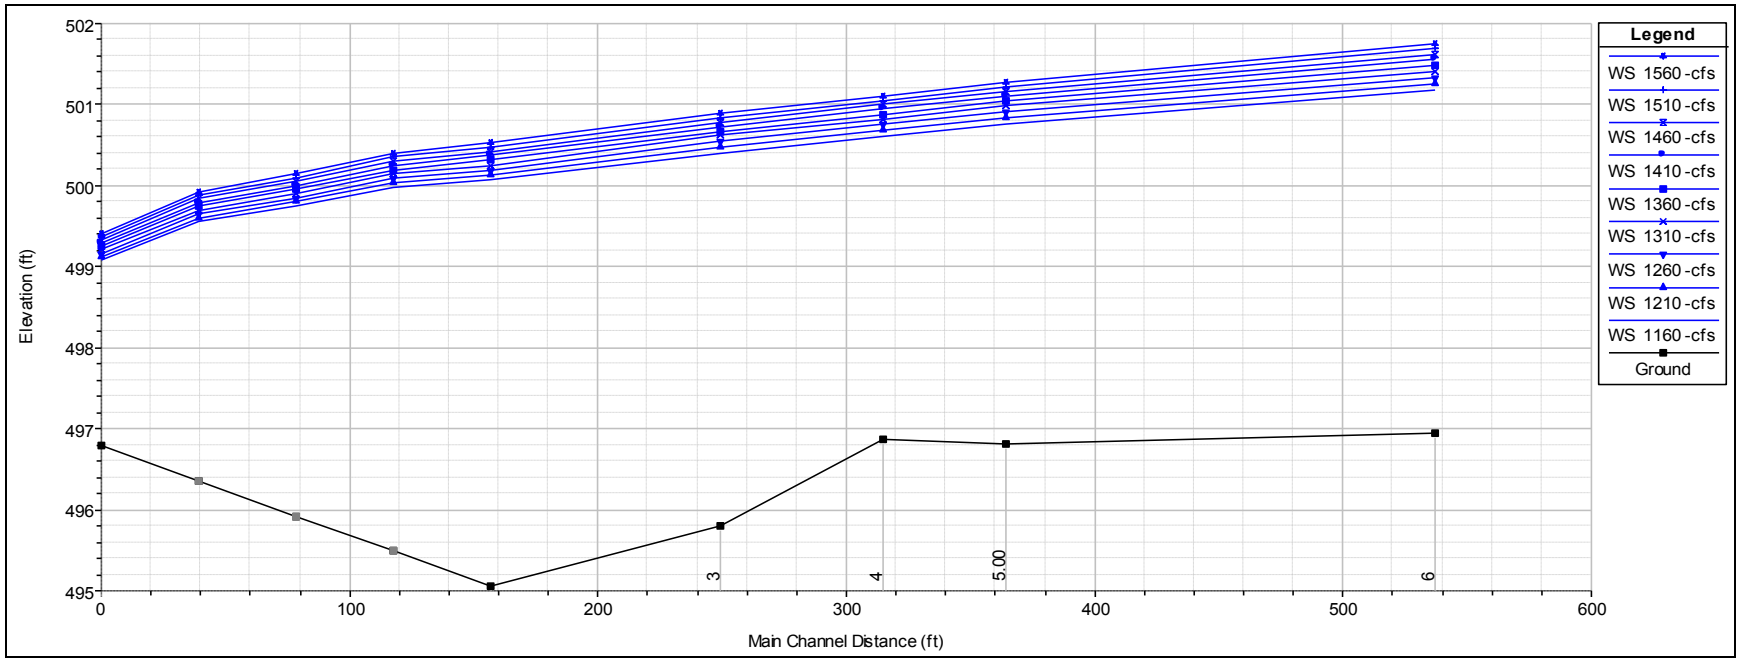

Figure 21 HEC-RAS longitudinal profile output for Reach FGNK3. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK3

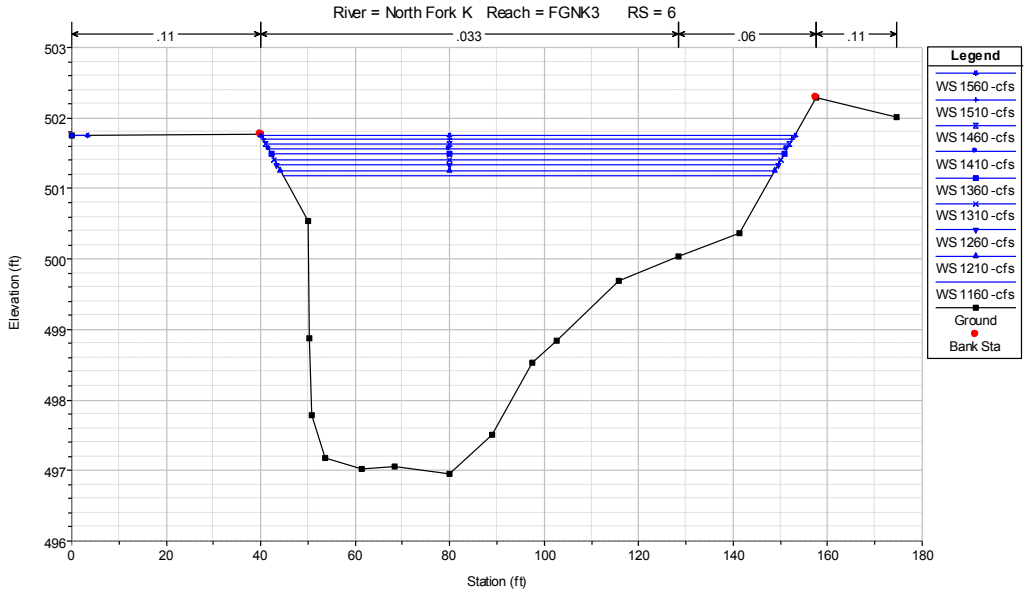

Figure 22 River Station (RS) 6 on River Reach FGNK3. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed five cross-sections along 490 feet of channel length. Section 1 serves as the downstream hydraulic control for the model. Sections 5 and 4 characterize the riffle which serves as the reference reach and through which the pebble count was taken. A bulk sample was taken upstream of Section 5. Obvious lag deposits were noted on site. A broad pebble count distribution further suggests the presence of lag. However the pebble count was not modified because the immobile size classes were not apparent in the distribution. FGNK4 is close to the 2006 out-of-channel sediment source survey site 06-NKSS11.3.

For a Shields number of 0.026, the D_{50} has begun to move by 1100 cfs for Section 5 and by 1250 cfs through Section 4. For a Shields number of 0.017, the D_{84} from this site does not move within the range of flows. The discrepancy in the incipient motion of the D_{50} and the D_{84} further suggests that some of the bed is made of immobile material which does not frequently make it through this reach. The origin of the larger particle sizes making up the surface sediment sample are suspected to come from the glacial outwash terrace 800 feet upstream from Section 5. It appears that the larger particles originating from the glacial terrace are depositing downstream and behave more similarly to lag deposits than those smaller particle sizes that have been better sorted further downstream. At 1250 cfs on Section 5 and 4, the incipient motion analysis suggests that for a Shields number of 0.017, particles of size 88 and 76 mm will begin movement, respectively. This particle size better represents the sediment distribution found in FGNK1 and FGNK2 (D_{84} of 85 and 73 respectively). Flows between 1100 and 1500 cfs match the inflection points on both the left and right banks of Section 4 and a flow of 1450 cfs matches an inflection point on the left bank of Section 3.

The reference reach sections (Sections 4 and 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed five cross-sections over 300 feet of stream. Section 1 serves as the downstream hydraulic control for the model and represents a break in slope downstream of a pool/glide. Sections 2 and 3 characterize the riffle. Since the riffle was short in length and located along a bend, the pebble count was conducted throughout the entire riffle between Sections 2 and 3. Since the hydraulics difference between Sections 2 and 3 were great, a section was interpolated within HEC-RAS (Section 2.5*) to account for the location of the pebble count in the incipient motion analysis. While the sediment found within the riffle is coarse, and there were obvious lag deposits on site, the pebble count distribution does not show any obvious signs of lag (immobile material). Bank material appears to be closer to what was observed on the bed of the lower North Fork Koktuli sections and that which was shown to be mobile within these sections.

This site shows poor convergence of the geometry and the incipient motion analysis. On Section 2.5, the D_{50} begins movement before 950 cfs for a Shields number of 0.026 while the D_{84} does not move within the range of flows. On Sections 3 and 5, the D_{84} is moving by 950 cfs and moves between 1200 and 1250 cfs on Section 4. The gravel bar along the right bank of the pool, Section 5 and 4, is overtopped at flows of 1100 cfs and 950 cfs respectively. The bench on the right bank of Section 3 is overtopped by 950 cfs while flows in Section 2 remain in the channel, reaching an inflection point around 1300 cfs. Due to the potential presence of immobile material and lack of analytical soundness in the incipient motion analysis, the range of flows is based on the geometry of the surveyed reach.

Due to the lack of convergence within this reach and the length and location of the riffle the reference reach was extended upstream so that channel width and cross-sectional area were averaged over Sections 6 through 3.

HEC-RAS OUTPUT SUMMARY TABLE: FGNK5

	% Willow	**65**	
	% Grass	**35**	
	% Tree	**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 840 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. A side channel along the left bank of the downstream hydraulic control was surveyed in as well. Due to its angle off the main channel and the size of the channel the momentum of the main channel causes this side channel to be ineffective during high flows. The left bank was therefore interpolated to complete Section 1. Sections 5 and 4 characterize the riffle which serves as the reference reach. The pebble count was taken through Section 5. Some lag was noted at this site, but was not evident in the pebble count. This site was co-located with the ISF site 05-NFK1-RFI.

The incipient motion analysis shows good agreement with the geometry of the site and the geomorphic indicators surveyed in. For a Shields number of 0.026, the D_{50} moves through Section 6 at 1050 cfs, before 800 cfs on Section 5 and does not move within the range of flows on Section 4. At Section 5, the D_{84} begins movement between 1000 and 1050 cfs with a Shields number of 0.017, but does not move through Section 4 within the range of flows. These flows match the inflection point on the right bank for Section 4.

The reference reach sections (Sections 4 and 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGNK6

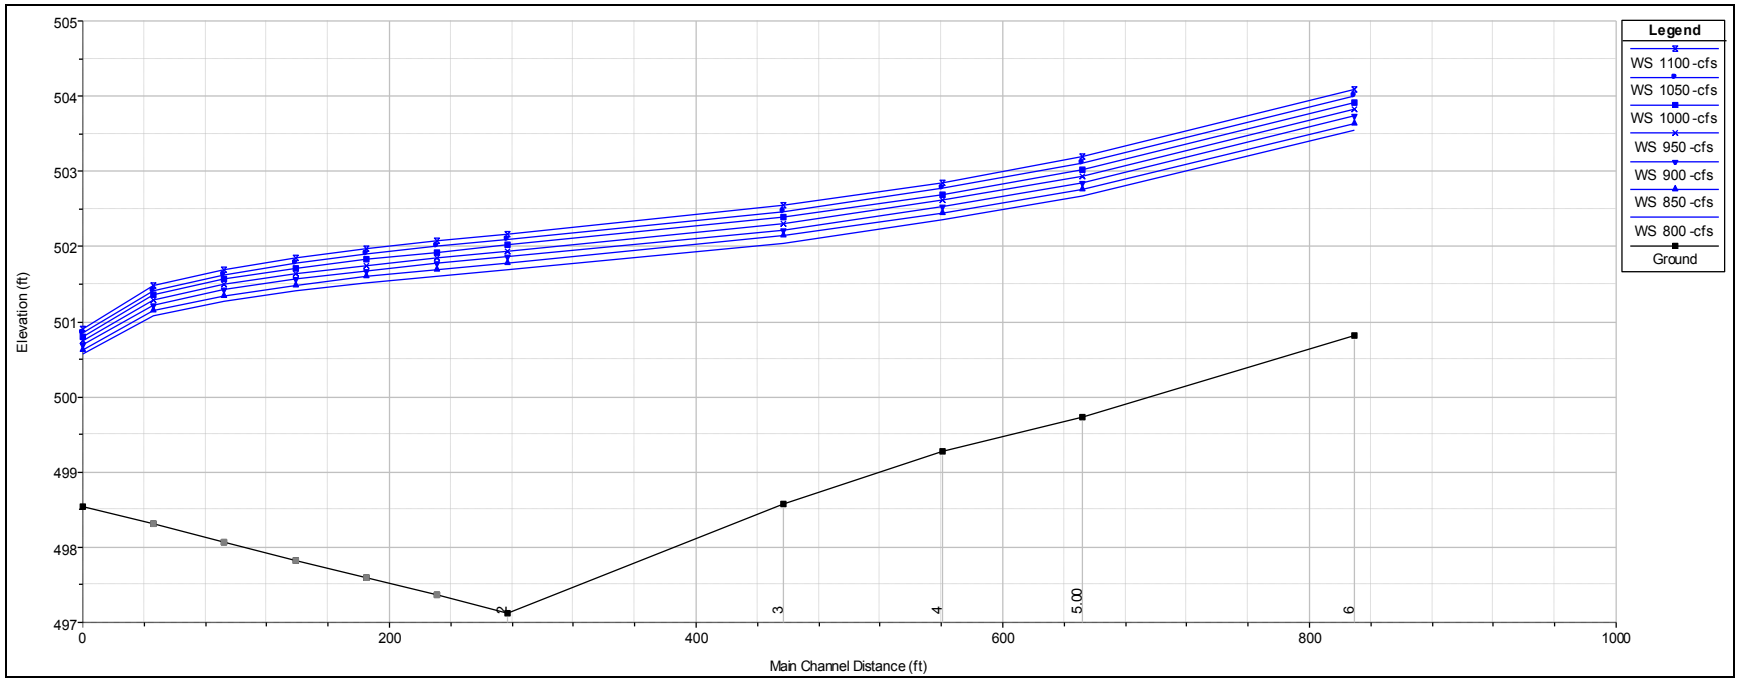

Figure 41 HEC-RAS longitudinal profile output for Reach FGNK6. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK6

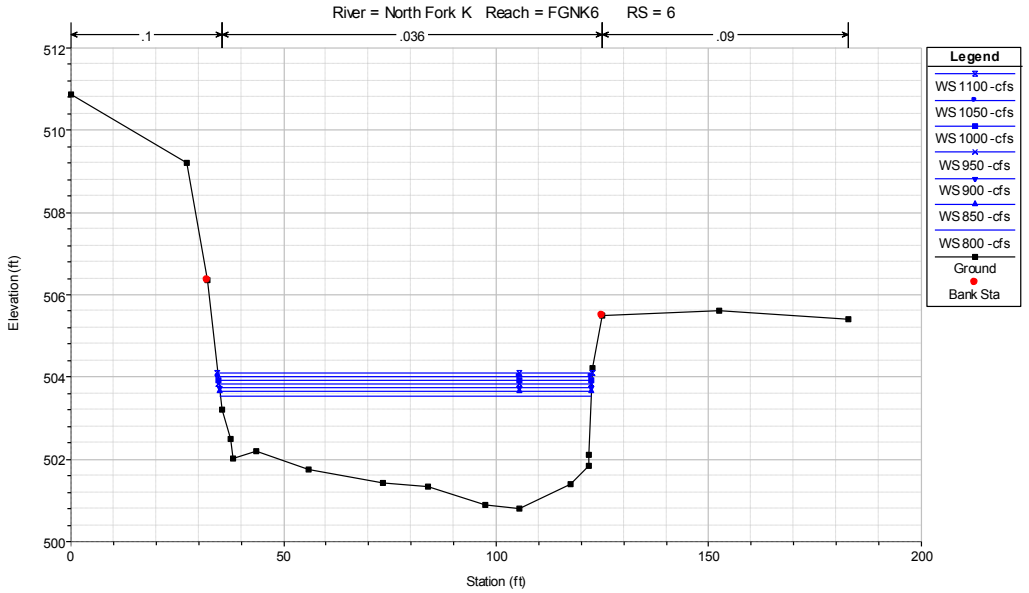

Figure 42 River Station (RS) 6 on River Reach FGNK6. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK6

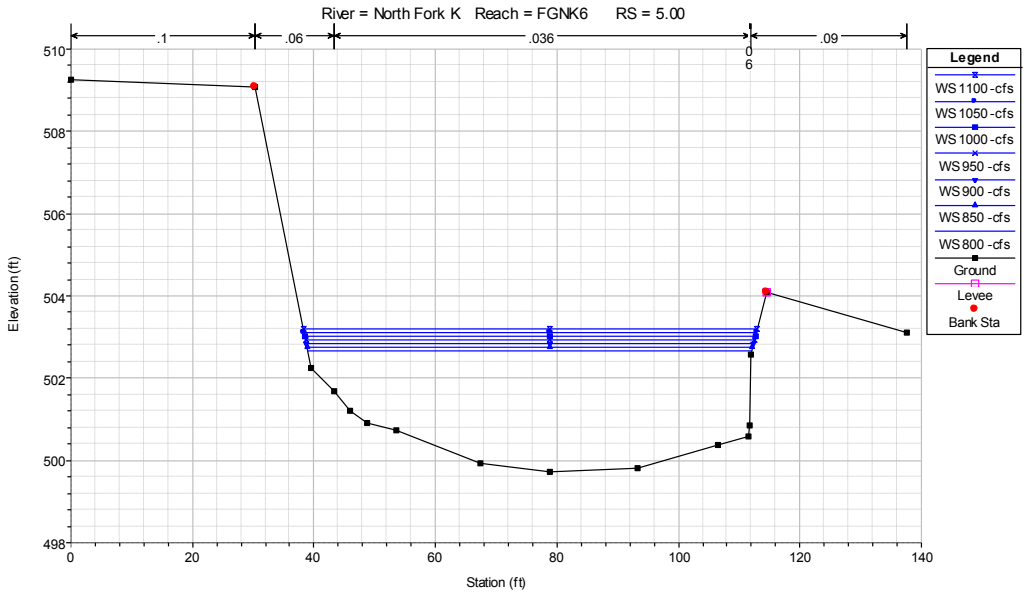

Figure 43 River Station (RS) 5.00 on River Reach FGNK6. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS OUTPUT: CROSS-SECTIONS

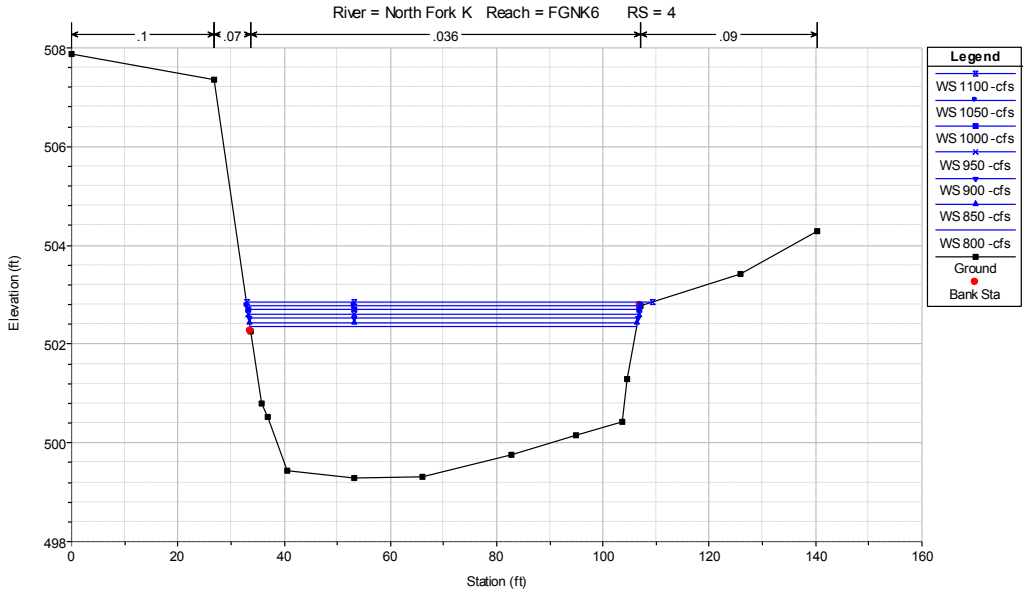

Figure 44 River Station (RS) 4 on River Reach FGNK6. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS OUTPUT: CROSS-SECTIONS

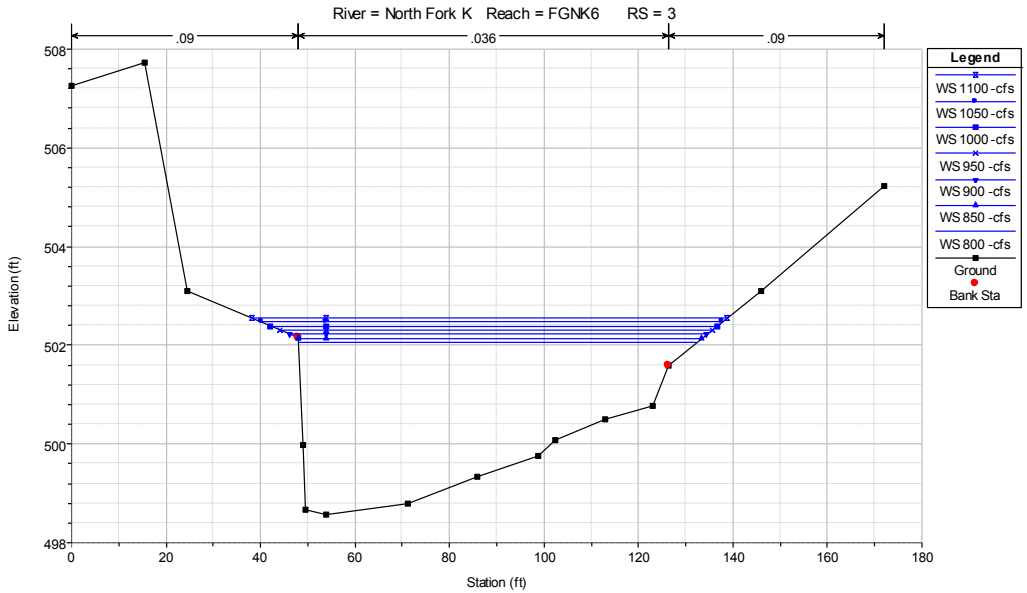

Figure 45 River Station (RS) 3 on River Reach FGNK6. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS OUTPUT: CROSS-SECTIONS

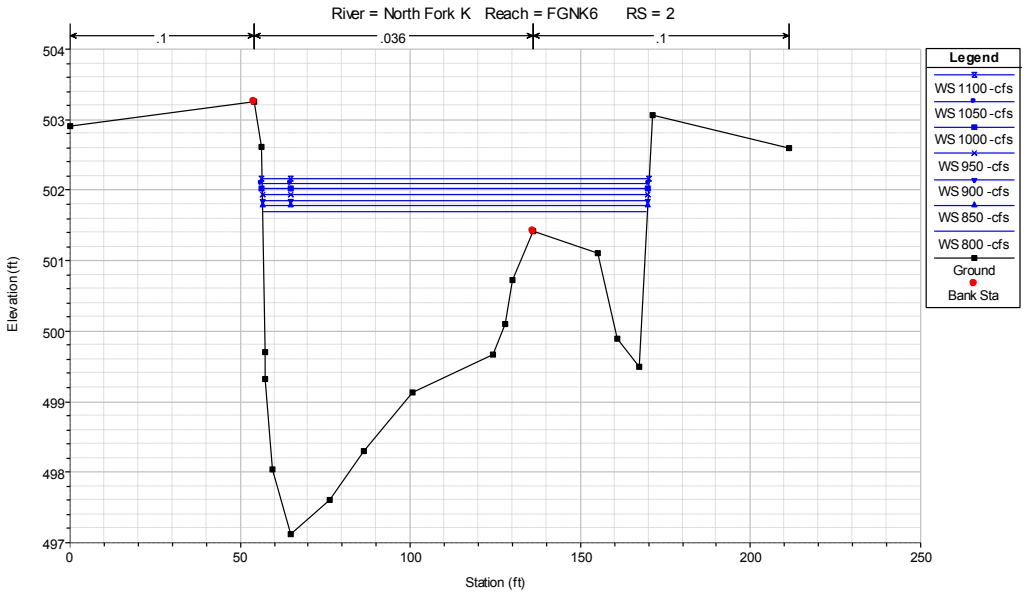

Figure 46 River Station (RS) 2 on River Reach FGNK6. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS OUTPUT: CROSS-SECTIONS

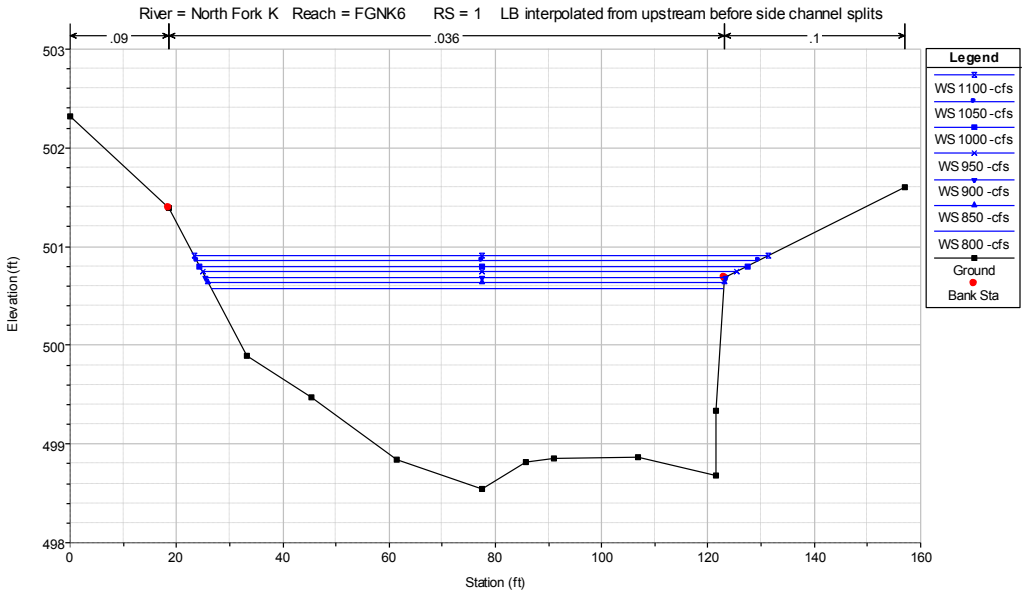

Figure 47 River Station (RS) 1 on River Reach FGNK2. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

% Willow	**70**		
% Grass	**30**		
% Tree	**0**		

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 650 feet of channel length. Section 1 serves as the downstream hydraulic control for the model. Sections 6 through 4 characterize the riffle which serves as the reference reach through which the pebble counts were taken. Pebble count 1 was taken upstream of Section 5, before the grade break represented by Section 5. Pebble count 2 was taken downstream of Section 5 in an area that was actively modified by fish. This site has substantial lag deposits as shown in the surface sediment sampled (note the broad pebble count distributions). The D_{50} and D_{84} size classes are nearly double those found in the lower North Fork Koktuli. To account for the potential lag, the pebble counts were modified by removing rocks greater than 256 mm (see below). However, this modification may not account for all of the lag present.

For Shields numbers of 0.017 and 0.026, the D_{84} and D_{50} (respectively) do not move through the reference reach within the range of flows that enter flood prone areas. However, within that range of flows, average rock sizes of 57 mm (Shields number of 0.026) and 87 mm (Shields number of 0.017) move. These particle sizes more closely represent the material size that makes up other lower North Fork Koktuli sites (FGNK1 and FGNK2). The channel appears to be in equilibrium with material moving through the channel. Due to the potential presence of immobile material in the incipient motion analysis, the range of flows is based on the geometry of the surveyed reach. Flows between 600 and 775 cfs match the geometry well through the reach, notably Sections 3 and 4 where 675 cfs match a right bank inflection point.

The reference reach (Sections 6 through 4) provides the best representation of the channel dimensions and was used to find average channel width and cross-sectional area over the range of flows

HEC-RAS OUTPUT SUMMARY TABLE: FGNK7

SITE DESCRIPTION: FGNK8

Site Characteristics.

Site Name		**FGNK8**	
Discharge (cfs)	**375 (325-525)**	Width (ft)	**57.9 (51.3-63.7)**
Slope	**0.0050**	Cross-sectional Area (ft^2)	**101 (75-125)**
D_{50}	**36**	D_{84}	**73**
Lat/Long Location	**N59.92610 W155.51178**	Drainage Area (mi^2)	**62**
	% Willow	**60**	
	% Grass	**40**	
	% Tree	**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 290 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and the crest of the pool. Sections 5 through 3 characterize the riffle which serves as the reference reach. The pebble count was taken through Section 5. Sections 3 through 1 characterize the pool, while Section 6 was taken to capture the run/glide upstream of the reference reach. Surface sediment is slightly smaller than that sampled in the lower river.

For a Shields number of 0.017, the D_{84} moves through Section 5 around 325 cfs and before 325 cfs on Sections 4 and 3. Similarly, for a Shields number of 0.026, the D_{50} moves through all of the reference reach sections (5 through 3) by 325 cfs. A flow between 325 and 375 cfs match an inflection point and the vegetative indicator on the left bank through the reference riffle. Higher flows (425-525 cfs) match right bank inflection points on Sections 3 and 2.

The reference reach sections (Sections 3 through 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

SITE DESCRIPTION: FGNK9

Site Characteristics.

Site Name	**FGNK9**		
Discharge (cfs)	**350 (310-500)**	Width (ft)	**45.8 (40.5-55.8)**
Slope	**0.0026**	Cross-sectional Area (ft^2)	**113 (83-153)**
(1) D_{50}	**43**	D_{84}	**78**
(2) D_{50}	**41**	D_{84}	**84**
Lat/Long Location	**N59.92610 W155.51178**	Drainage Area (mi^2)	**51**
% Willow	**40**		
% Grass	**60**		
% Tree	**0**		

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 300 feet of channel length. Section 1 serves as the temporary downstream hydraulic control for the model and the crest of the pool. Sections 6 through 4 characterizes the riffle which serves as the reference reach through which the pebble counts were taken; pebble count 1 was taken through Section 4 and pebble count 2 was taken through Section 6. Sections 4 through 1 characterize the pool. Sediment size fractions were very similar to those found in FGNK1 and FGNK2.

Mobility of the D_{84} and D_{50} through the reference reach bracket the range of channel forming discharges well. For a Shields number of 0.017, the D_{84} of both pebble counts begins to move between 350 and 410 cfs through Section 4 and between 435 and 500 cfs on Section 5. For a Shields number of 0.026, the D_{50} moves between 310 and 385 cfs through the lower sections of the reference reach (Sections 5 and 4). These results correlate well with the geometry and field indicators of channel-forming flow.

The reference reach sections (Sections 4 through 6) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGNK9

HEC-RAS LONGITUDINAL PROFILE: FGNK9

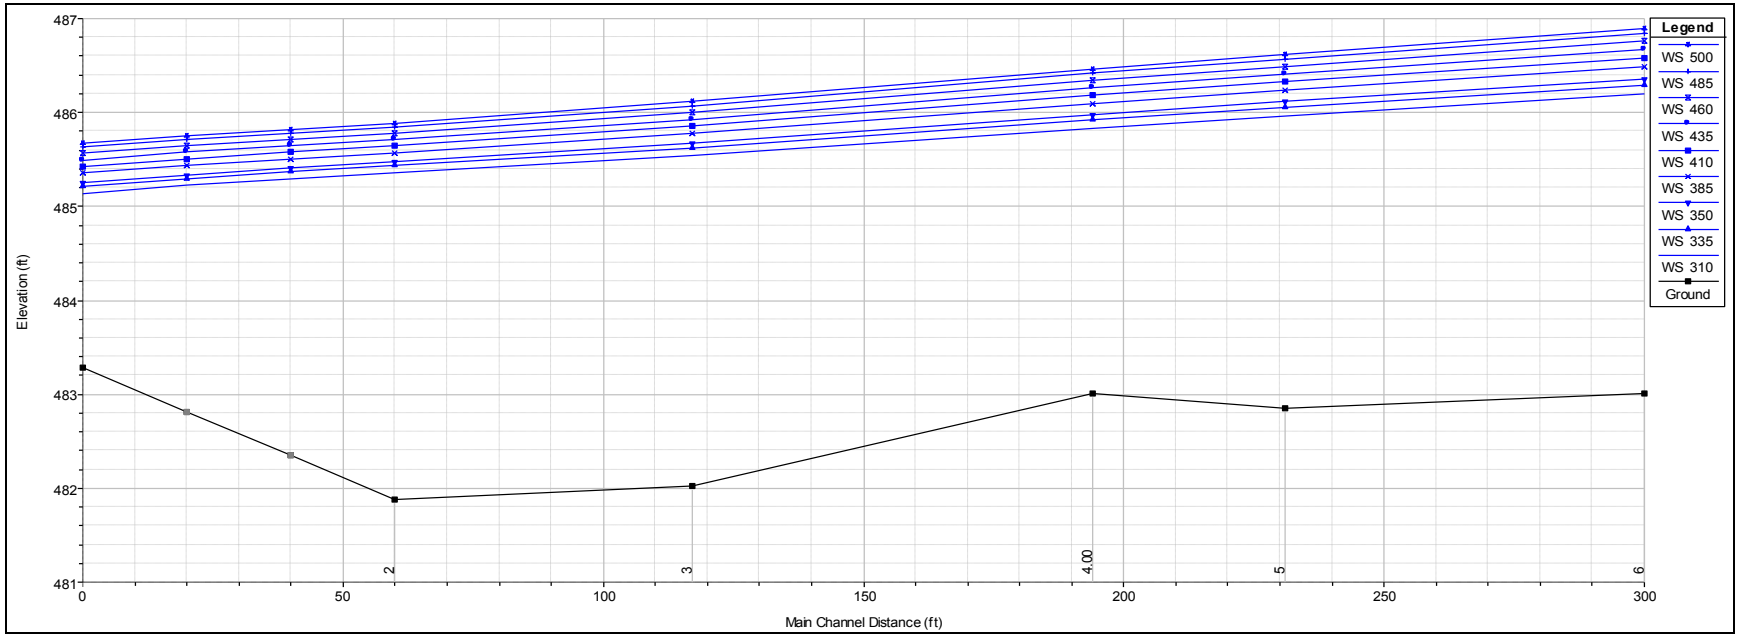

Figure 62 HEC-RAS longitudinal profile output for Reach FGNK9. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK9

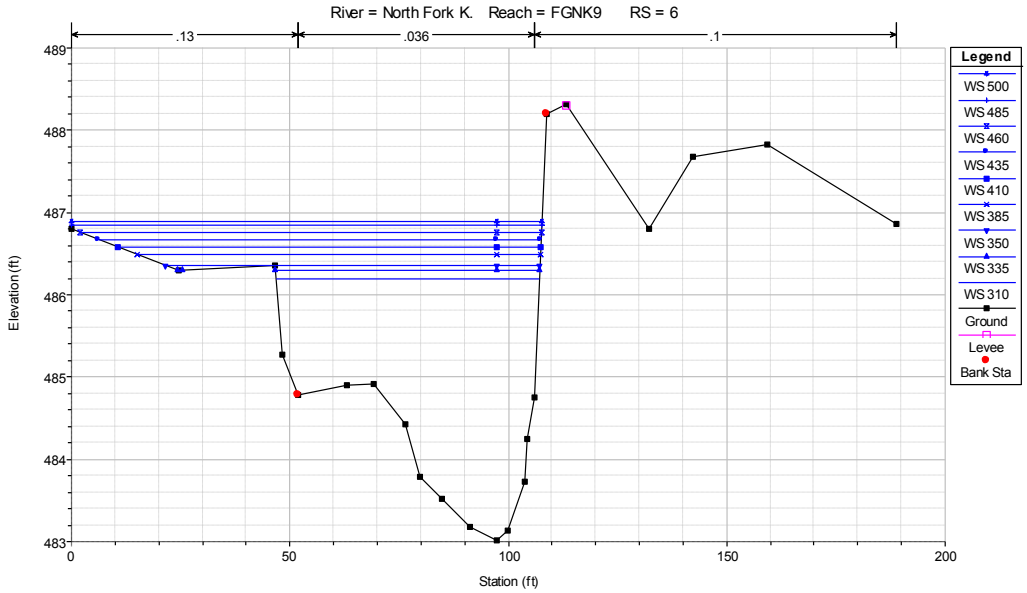

Figure 63 River Station (RS)6 on River Reach FGNK9. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK9

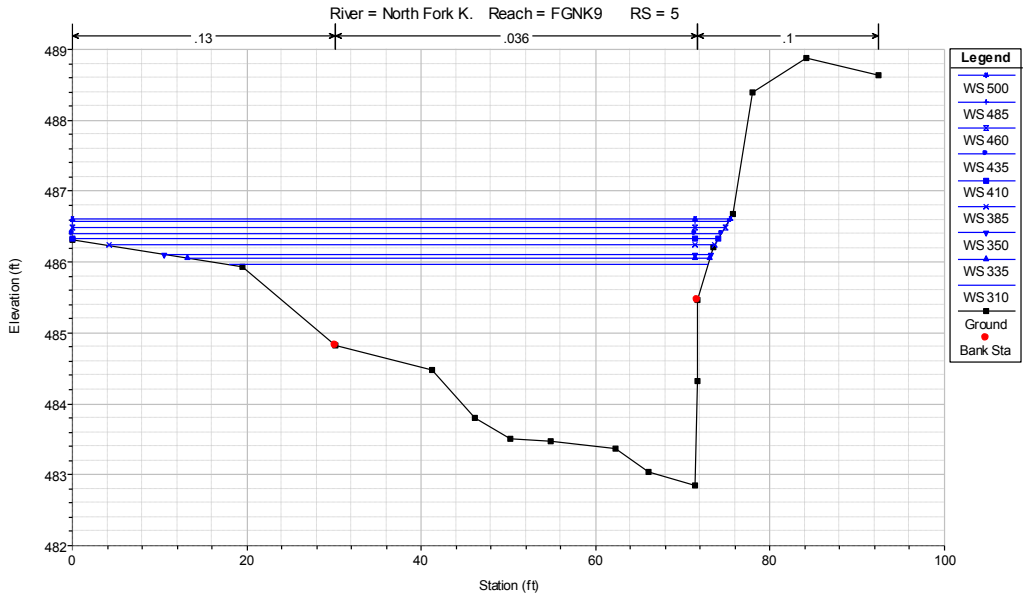

Figure 64 River Station (RS) 5 on River Reach FGNK9. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK9

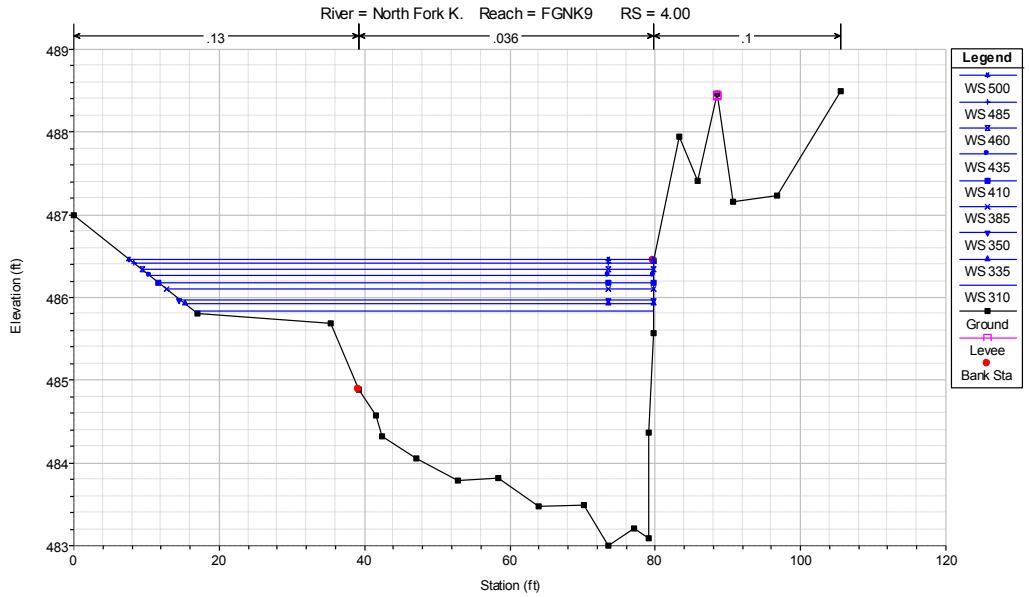

Figure 65 River Station (RS) 4 on River Reach FGNK9. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK9

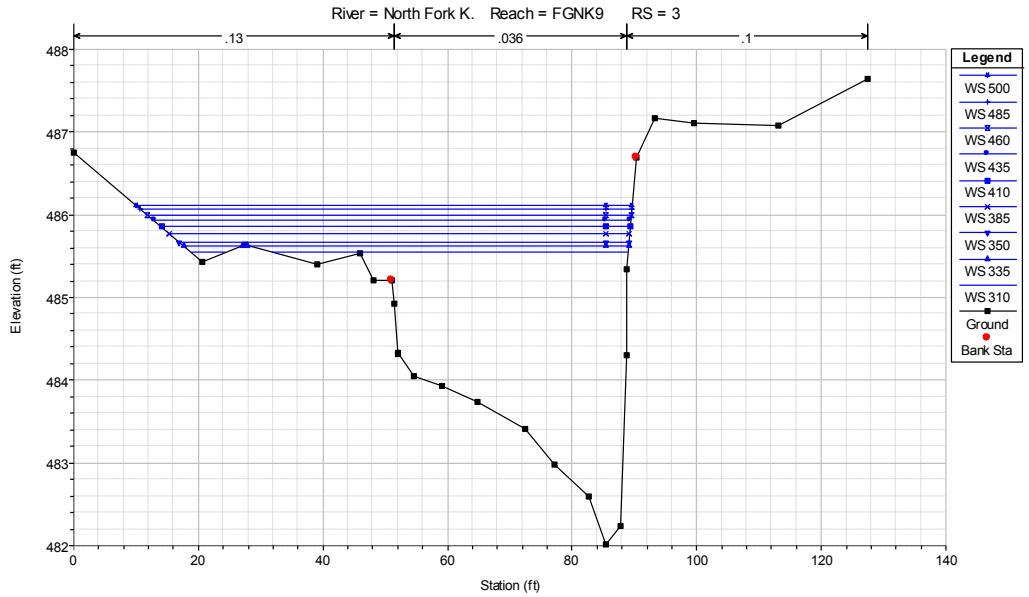

Figure 66 River Station (RS) 3 on River Reach FGNK9. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK9

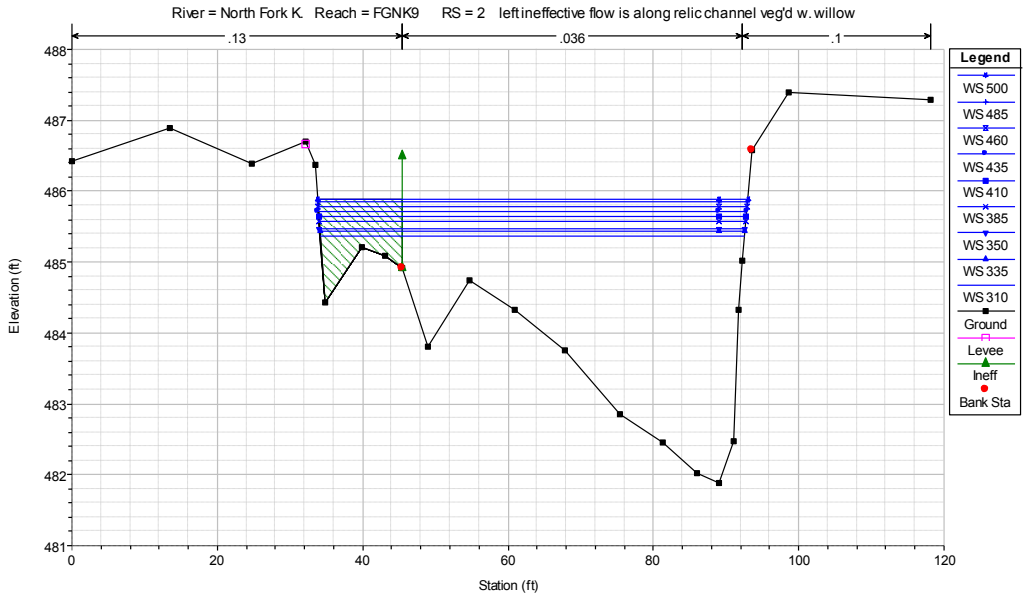

Figure 67 River Station (RS) 2 on River Reach FGNK9. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 540 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 8 through 6 characterize the riffle which serves as the reference reach. The pebble count was taken along Section 7. This particular riffle was steep, fairly wide, and comprised of large material. Both the left and right banks were low with mature willows. Section 5 was over widened by a groundwater channel along the left bank, and required the addition of an ineffective flow boundary to account for the lack of conveyance during high flows. From Section 5 on downstream, the channel takes a sharp right turn, forming a deep pool along the left bank were gravel is deposited to bar along the right bank. This gravel bar supports willow bands from young to mature moving away from the river. The width of the pebble count distribution suggests that this site has some lag or generally immobile material. Particles in the >256 mm size class were removed, as they were suspected to be immobile. The modified distribution was used in the following analysis.

The incipient motion analysis through Sections 8, 7 and 6 for a Shields number of 0.017 supports the observation of immobile material. For a Shields number of 0.017, the D_{84} does not move within our range of flows through the reference reach (Section 8 through 6). At a flow of 360 cfs, movement of 124 mm on average can be expected. These mobility results still do not match the D_{84} of the modified distribution, further suggesting the presence of lag beyond what was accounted for in the modified distribution. Geometrically, 360-390 cfs matches the inflection point along the left bank through the reference reach.

The reference reach sections (Sections 8 through 6) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGNK10

% Willow	**70**		
% Grass	**30**		
% Tree	**0**		

Site Overview. Chosen for its proximity to the HDR gage NK100C, the analysis of FGNK11 is calibrated to the roughly 2 years of hydrology data (7/04 – 6/06), allowing for an estimation of the frequency and magnitude of discharge events (see attached hydrograph).

During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 230 feet of channel length. Section 1 serves as the temporary downstream control for the hydraulic model. FGNK11 represents a fairly continuous and relatively steep reach with riffles/runs alternating with scour holes. A fair amount of lag provides structure to this alternating form. Cross-Sections 7 and 6 characterize the riffle which serves as the reference reach. The pebble count was taken through Section 6. The broad distribution of the surface sediment indicates the presence of lag. Particles in the >256 mm and 256 mm size classes were removed, as they were suspected to be immobile. The modified distribution was used in the following analysis.

While the mobility of the D_{50} shows agreement with the channel geometry and field indicators of channel forming discharges, the D_{84} is effectively immobile, further suggesting the presence of lag beyond what was accounted for in the modified distribution. For a Shields number of 0.026, the D_{50} moves between 300 and 350 cfs through Sections 7, 6, and 4. Flows between 250 and 275 cfs match the geometry well, notably through the upper sections (7 and 6). This range of flows correlates well with the hydrograph which within the two-year period of record has matched or exceeded the nominal flow of 300 cfs.

The reference reach sections (Sections 7 and 6) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGNK11

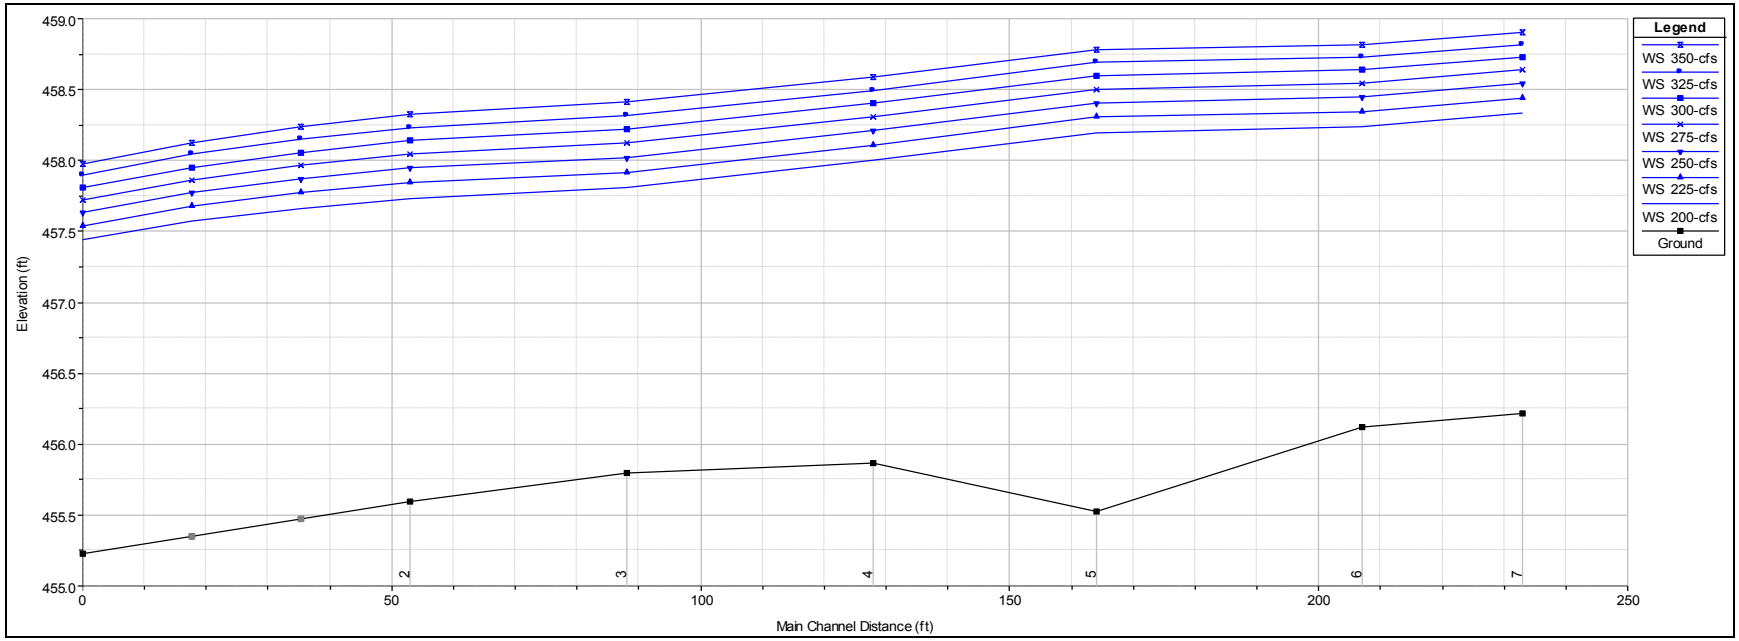

Figure 78 HEC-RAS longitudinal profile output for Reach FGNK11. Numbers 1-7 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 530 feet of channel length. No hydraulic controls or bedforms were observed along the reach. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections were surveyed in at changes in vegetation and channel shape and to capture bends. The bed was extremely loose consisting of mostly fines with some gravel. Long filamentous algae grew across most of the channel. A pebble count was conducted across Section 6 where gravels were slightly more apparent. Sedges and grasses grew along the channel margins, while willows grew on the higher banks.

Even at highest flows modeled, the incipient motion analysis showed no movement of the D_{84} at Shields values 0.017. For a Shields number of 0.026, the D_{50} moves through Sections 6 and 2 at flows of 250 and 275 cfs respectively. The slope through the reach was extremely low (0.0009) causing shear to remain low. The lack of movement of the sediment might be a Shields number issue, for example, it might be lower than 0.017. Most likely this reach functions differently than the rest of the North Fork Koktuli. The banks lack gravels found throughout the downstream sites. A flow of 225 cfs matches a left bank inflection along Sections 6 and 5 and 250 cfs matches an inflection point on the left bank on Section 2. The range of flows fits within the geomorphic indicators found along the reach.

Lacking any well-defined riffle, channel width and cross-sectional area were averaged over all of the surveyed sections, with the exception of Section 1, for the range of flows.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed 10 cross-sections along 260 feet of channel length. Section 1 serves as the temporary downstream hydraulic control for the model and represents the crest of the pool. Sections 6-10 represent the riffle which serves as the reference reach. Lag sediments were noted in the field and pebble count 1, sampled between Section 8 and 9, has a wide distribution, also suggests the presence of lag. Rocks in the 256 mm and the greater than 256 mm categories were removed from pebble count 1 in an attempt to remove the immobile fractions from the incipient motion analysis. Pebble count 2 was taken between Sections 6 and 7.

Bed mobility varies considerably through this reach. In the upper sections of the reference reach (Sections 10 and 9) for a Shields number of 0.017, the D_{84} of pebble count 2 moves between 200 and 275 cfs and for a Shields number of 0.026, the D_{50} moves by 200 cfs. The middle two sections of the reference reach (Sections 8 and 7) are not able to move the D_{84} and can only move the D_{50} on Section 8 at 300 cfs from pebble count 2 while Section 6 moves both size classes by 200 cfs. The D_{84} from pebble count 1 is effectively immobile through the reference reach for the range of channel forming discharges further suggesting the presence of lag beyond what is accounted for by the modified distribution. Flows between 225 and 275 cfs match the geometry well, notably the right bank through the reference reach.

The reference reach sections (Sections 6-10) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGNK13

HEC-RAS LONGITUDINAL PROFILE: FGNK13

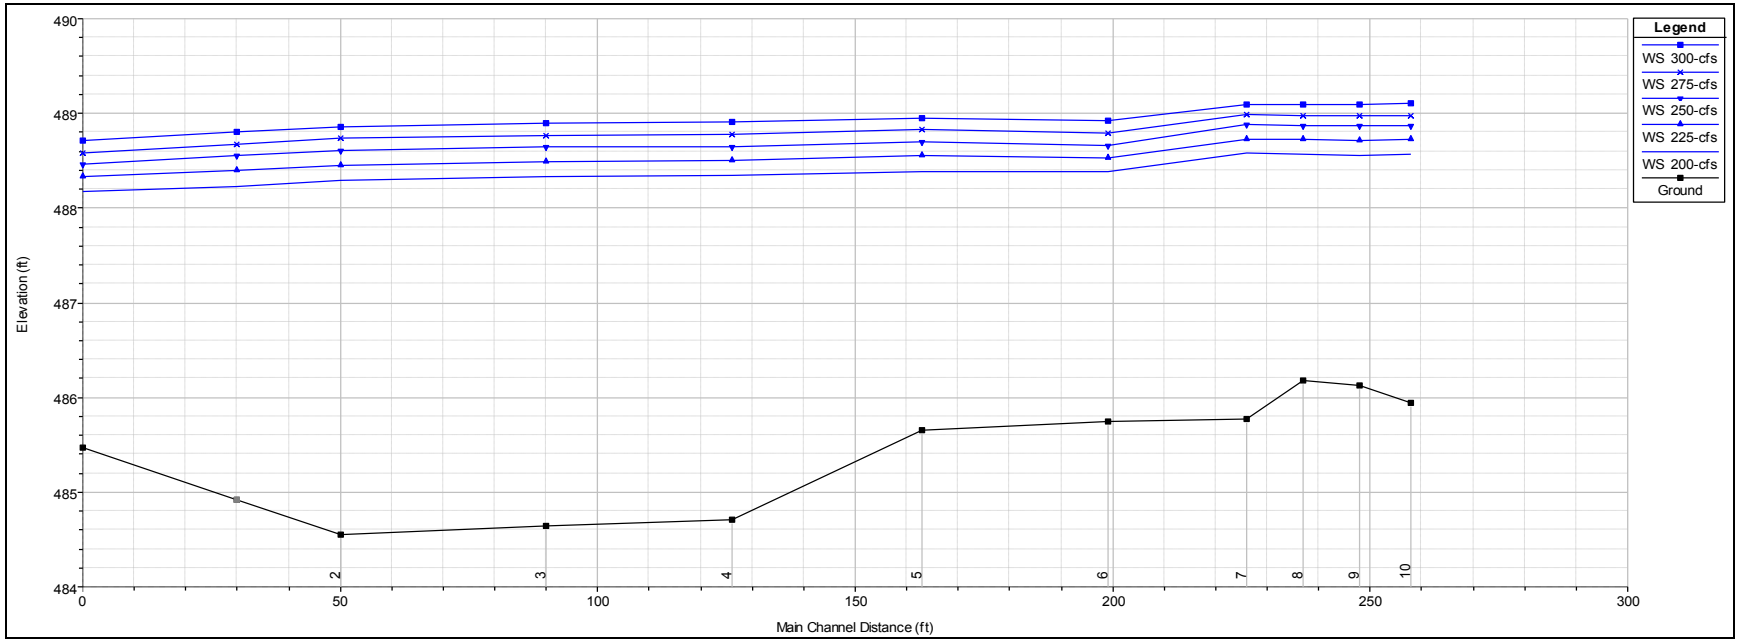

Figure 94 HEC-RAS longitudinal profile output for Reach FGNK13. Numbers 1-10 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK13

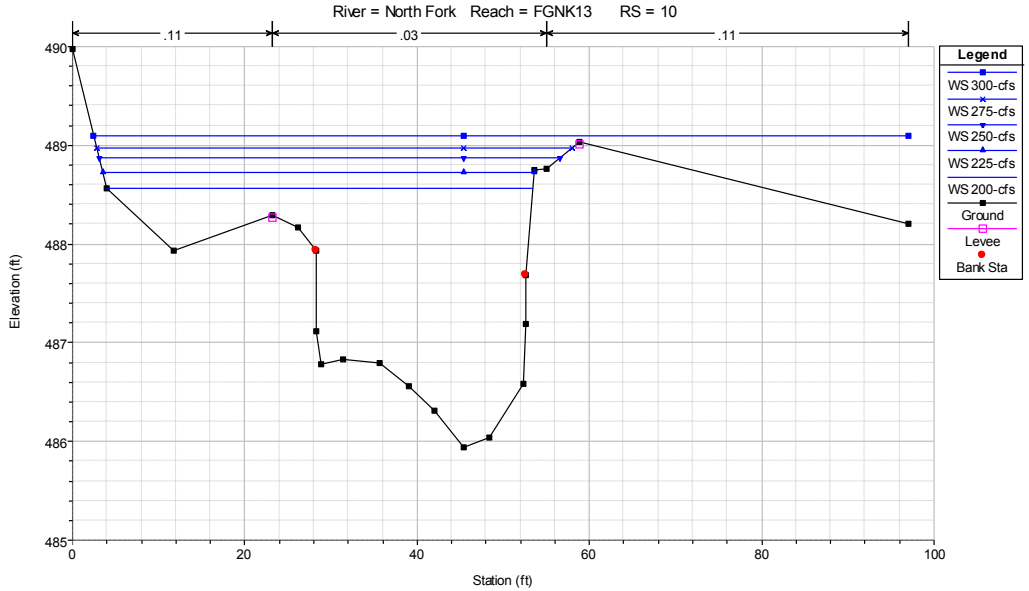

Figure 95 River Station (RS) 10 on River Reach FGNK13. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

	% Willow	**15**	
	% Grass	**85**	
	% Tree	**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 120 feet of channel length. Section 1 serves as the temporary downstream hydraulic control for the model and the crest of the pool. Sections 5 through 4 characterize the riffle which serves as the reference reach through which the pebble count was taken. Sections 4 through 1 characterize the pool.

The incipient motion analysis show strong agreement within the reference reach (Sections 4 and 5). For a Shields number of 0.017, the D_{84} particle begins movement between 160 and 175 cfs and for a Shields number of 0.026, the D_{50} is mobile by 135 cfs. For a Shields number of 0.017, the D_{84} is also mobile through Section 6 at a flow of 160 cfs. While the geometry and field indicators of channel forming discharges (including natural levees) through the reference reach match flows closer to 185 cfs or greater, the bed mobility was more convincing. Features like levees may be a remnant of a recent large flood. Through the lower pool sections (3 through 1), the range of channel forming discharges matches the top of the gravel bar well.

The reference reach sections (Sections 4 and 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGNK14

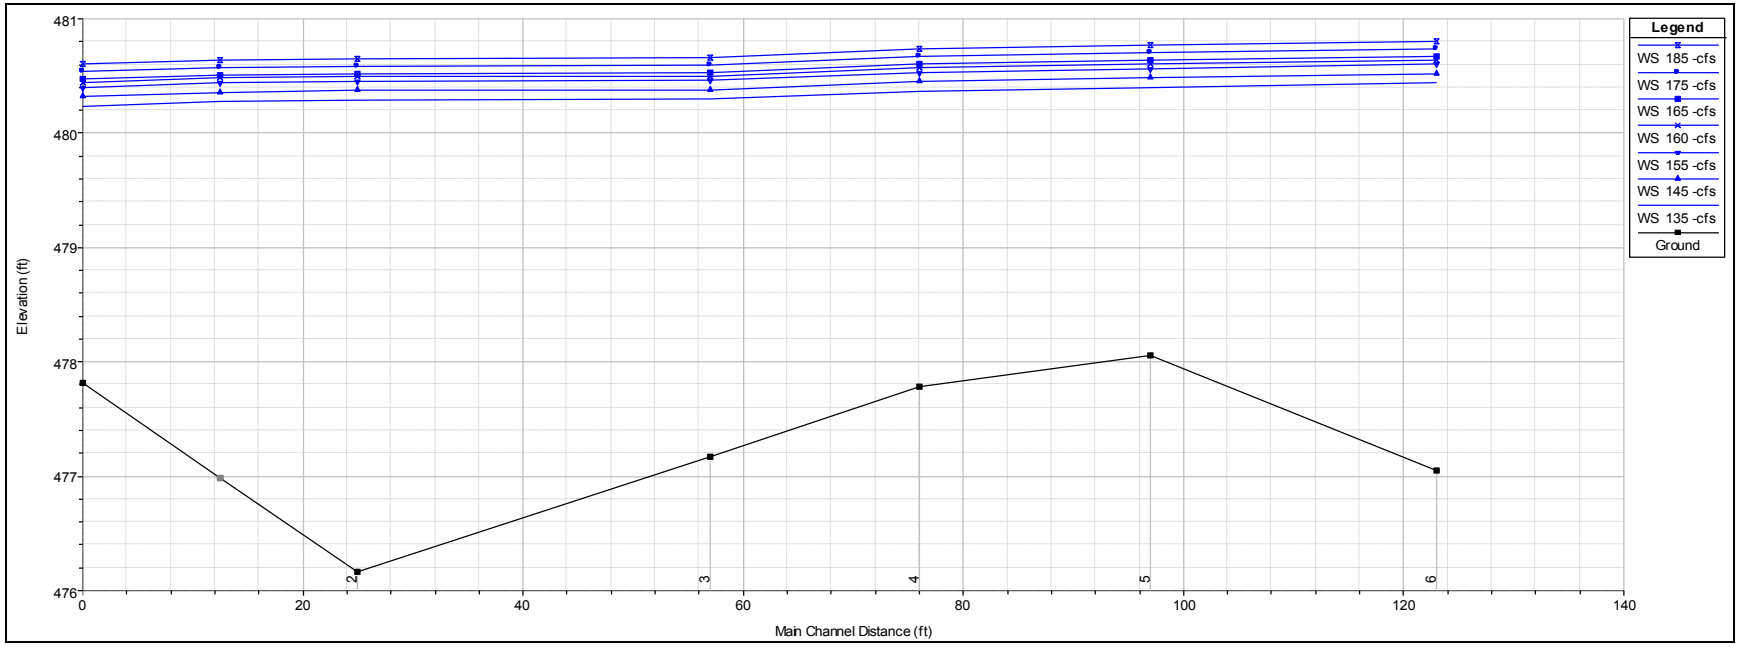

Figure 105 HEC-RAS longitudinal profile output for Reach FGNK14. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK14

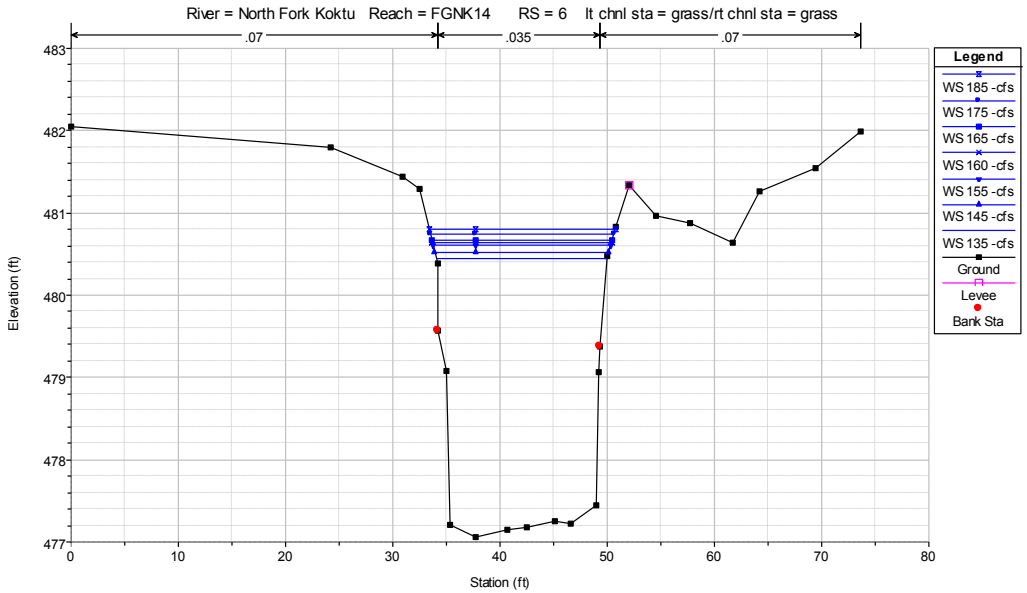

Figure 106 River Station (RS) 6 on River Reach FGNK14. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK14

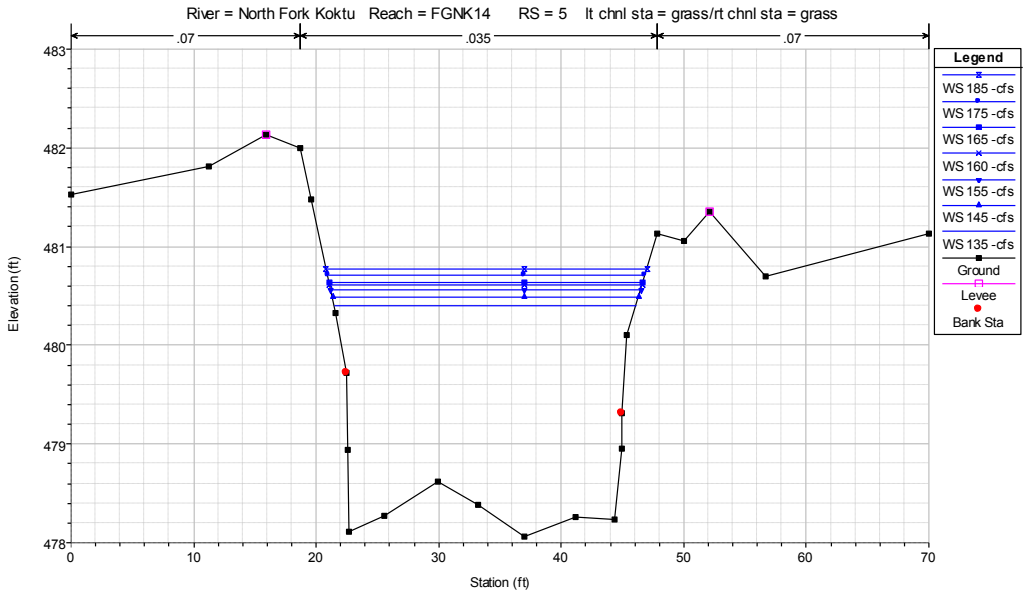

Figure 107 River Station (RS) 5 on River Reach FGNK14. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGNK14

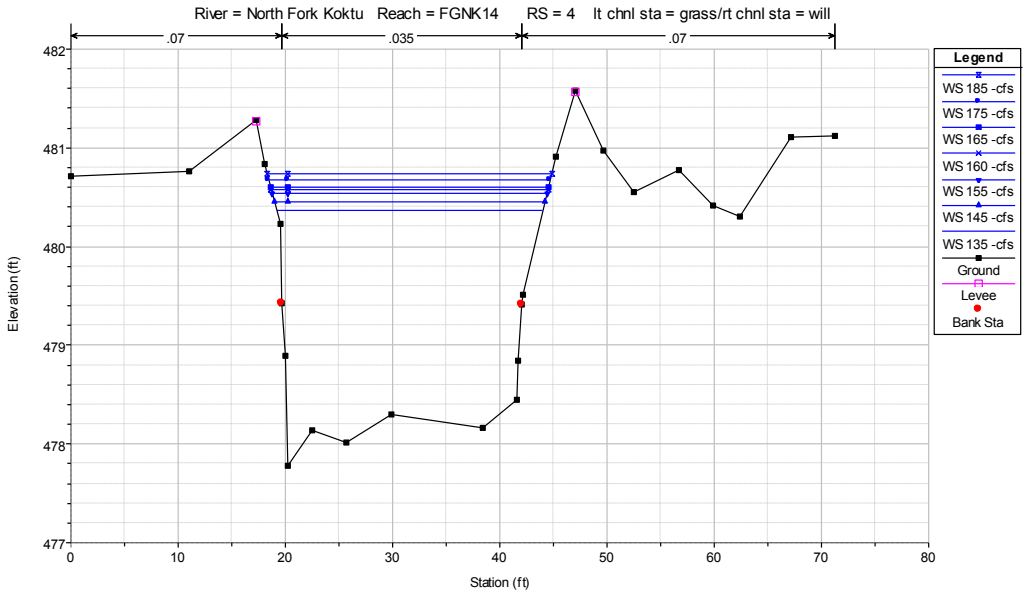

Figure 108 River Station (RS) 4 on River Reach FGNK14. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

SITE DESCRIPTION: FGNK15

Site Characteristics.

Site Name	**FGNK15**		
Discharge (cfs)	**160 (140-180)**	Width (ft)	**16.6 (15.7-18.1)**
Slope	**0.0084**	Cross-sectional Area (ft^2)	**32 (29-39)**
D_{50}	**50**	D_{84}	**117**
Lat/Long Location	**N59.96288 W155.28932**	Watershed Area (mi^2)	**6**
% Willow	**20**		
% Grass	**80**		
% Tree	**0**		

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 150 feet of channel length. Section 1 serves as the temporary downstream hydraulic control for the model and represents the crest of the pool. Sections 8 through 4 characterize the riffle which serves as the reference reach. Multiple grade breaks through the reference reach were captured with these sections. The pebble count was taken between Sections 7 and 6. The substrate comprising the channel bed was not as loose as that of other sites along the North Fork Koktuli.

Using the higher end of Shields numbers found with the Radio Rock Study, 0.026 which is a value closer to those reported for gravel-bed rivers in the lower 48 states, for the incipient motion analysis, the D_{84} moves at 150 cfs through Section 5 and before 140 cfs through Section 4 within the reference reach. Flows between 160 and 170 cfs match an inflection point along the entire reference reach.

The reference reach sections (Sections 8 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

% Grass		**50**	
% Tree		**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 140 feet of channel length. Sections 1 and 2 serve as the temporary downstream hydraulic control for the model and represent the crest of the pool as it transitions to a transverse riffle. Sections 7 through 5 characterize the riffle which serves as the reference reach. The channel turns to the right downstream of Section 5 and dropping into a pool at Section 4. According to the model, this drop creates supercritical flow through Section 4 (the pool). By Section 5, the downstream boundary condition and hydraulics through the pool have stabilized. Therefore, this analysis focused on the upstream three sections through the reference reach.

The variability in the incipient motion analysis and cross-section geometry is represented by the range of flows chosen. At cross-Section 7 and 6 for a Shields number of 0.017, the D_{84} particle moves close to a flow of 165 cfs, and for a Shields number of 0.026, the D_{50} moves before125 cfs through Sections 6 and 5. A flow of 125 cfs matches the inflection points well on cross-Section 5 as well as an inflection point found on the right bank of both Section 6 and 7. A flow of 165 cfs matches an inflection point on the left bank for both Sections 6 and 7.

The reference reach sections (Sections 7 through 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGNKt-1

(modified) D_{50}	**40**	D_{84}	**80**
Lat/Long Location	**N59.82210 W155.76777**	Drainage Area (mi^2)	**105**
% Willow	**80**		
% Grass	**20**		
% Tree	**0**		

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 650 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 6 through 4 characterize a riffle which serves as the reference reach. The left bank through the riffle and downstream to Section 3 is a high terrace that is being undercut contributing large gravel to the stream. Between Sections 3 and 4 is an exposed portion of the terrace actively being eroded away by the river. The right bank through the riffle was well defined with mature willows and grass.

An HDR stream gage (SK100A) downstream of the site, just upstream of the confluence with the North Fork Koktuli, provided roughly two years of hydrology data (07/04 – 06/06) to compare the range of channel forming discharges determined for this site. Due to the suspected presence of lag, the pebble count was adjusted. Those rocks in the 256 mm and the greater than 256 mm (one each) were removed. Based on a Shields number of 0.017, the D_{84} moves in Section 6 and 5 at discharges of 850 and 800 cfs respectively, while the critical shear to move the D_{50} for a Shields of 0.026 has already been exceeded by 800 cfs. Flows of 1000 cfs and 850 cfs match the right bank inflection points for Section 6 and 5 respectively. Additionally, flows between 900 and 950 match the right bank inflection points through the pool (Section 3 and 2).

The reference reach, which include riffle Sections 6 through 4, provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGSK1

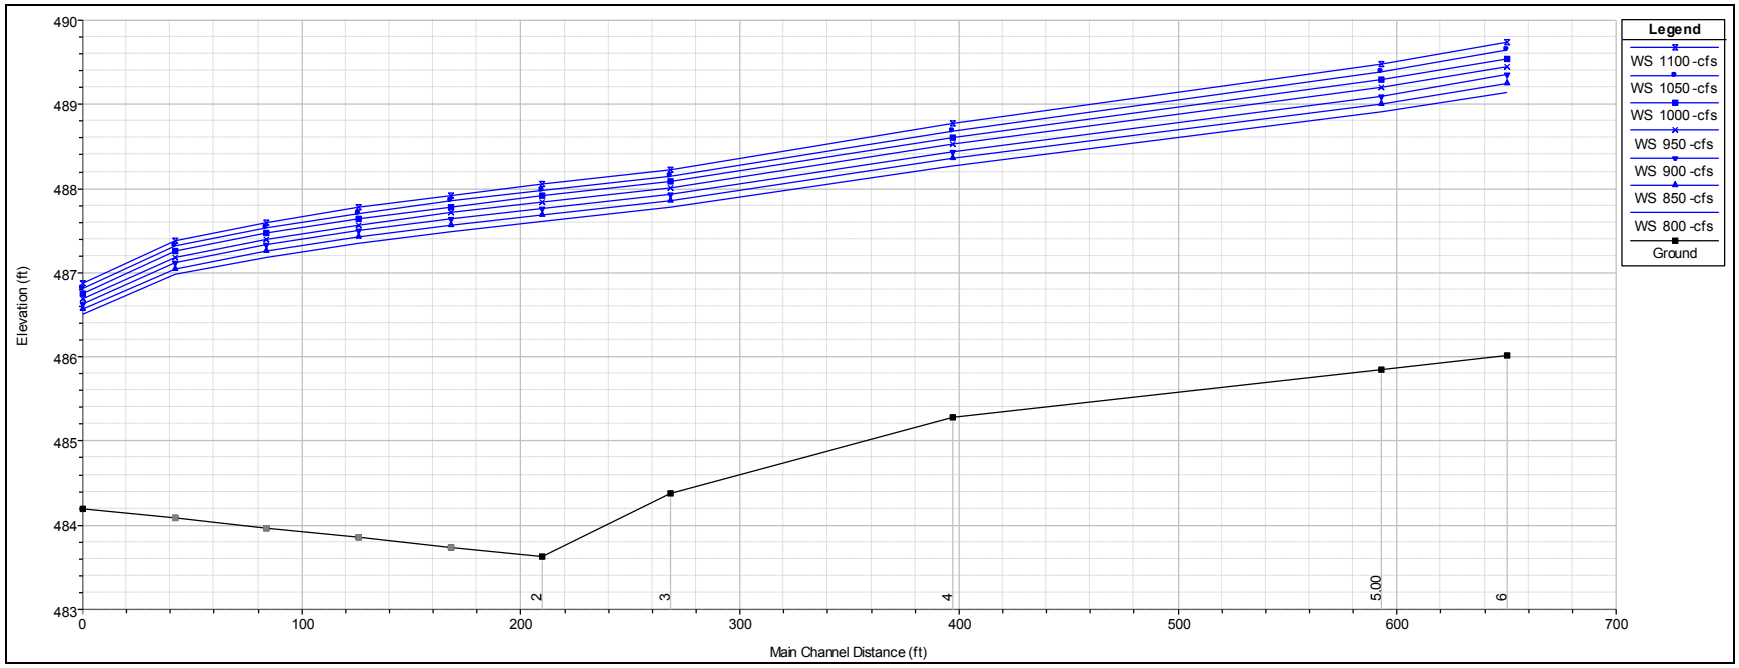

Figure 1 HEC-RAS longitudinal profile output for Reach FGSK1. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK1

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 430 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 5 and 4 characterize a riffle located along a bend. Pebble count 1 was taken across River Station (RS) 4 which may be overly wide due to its location potentially causing ineffective flow. As another indicator of channel-forming flows, another section upstream was surveyed. Section 6 characterizes a glide upstream of the riffle which is a straight stretch with well-formed banks. Pebble count 2 was taken through this glide. The reference reach includes Sections 6 through 4. Sections 4 through 1 characterize the pool.

For a Shields number of 0.017, the D_{84} of pebble count 1 begins to move from Section 4 by 600 cfs while the D_{84} of pebble count 2 begins to move at a discharge of 850 cfs. A discharge of 700 cfs matches the geometry of Section 6 well and discharges between 600 and 700 cfs match the geometry of Sections 5 and 4.

The reference reach including a riffle and upstream glide sections (Sections 6 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGSK2

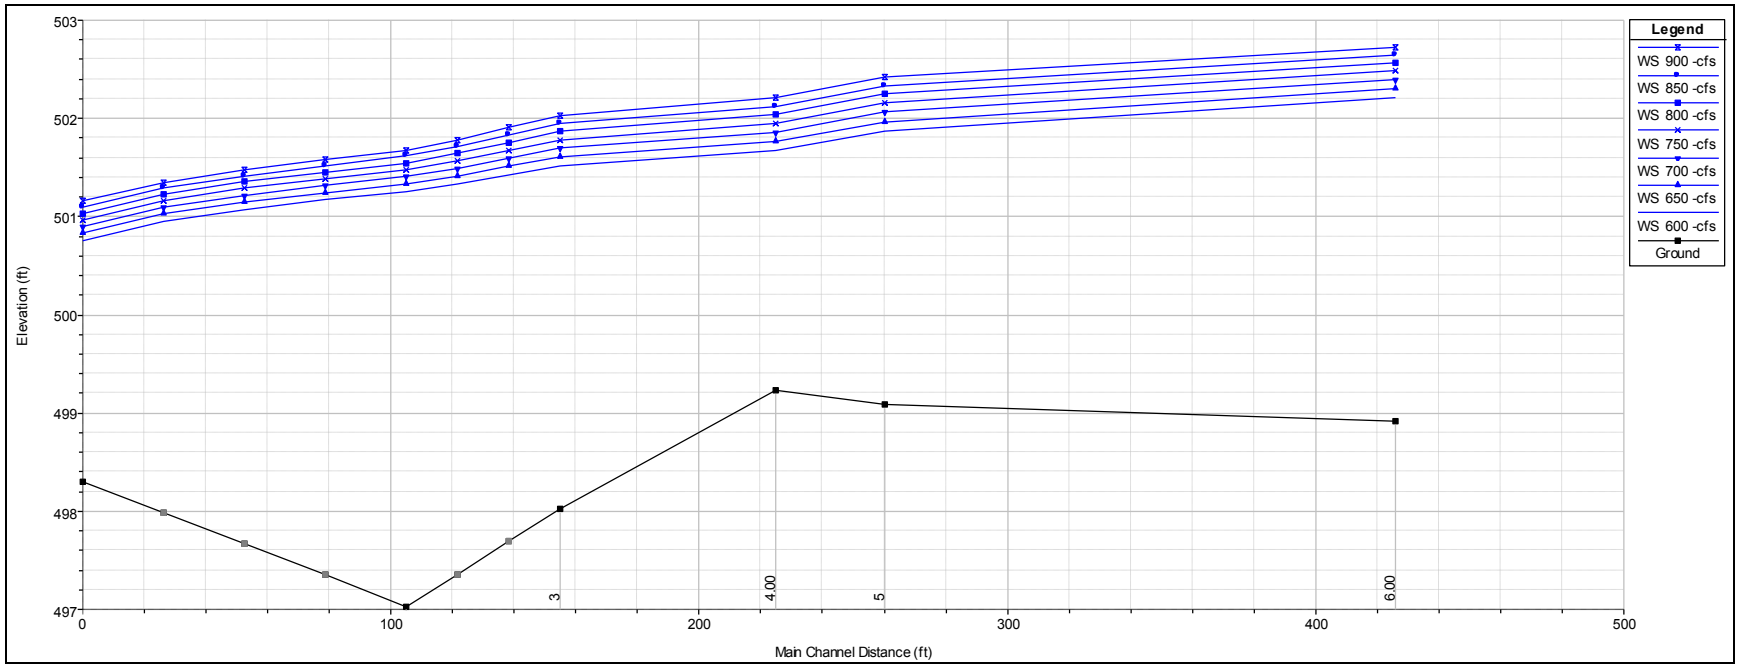

Figure 9 HEC-RAS longitudinal profile output for Reach FGSK2. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK2

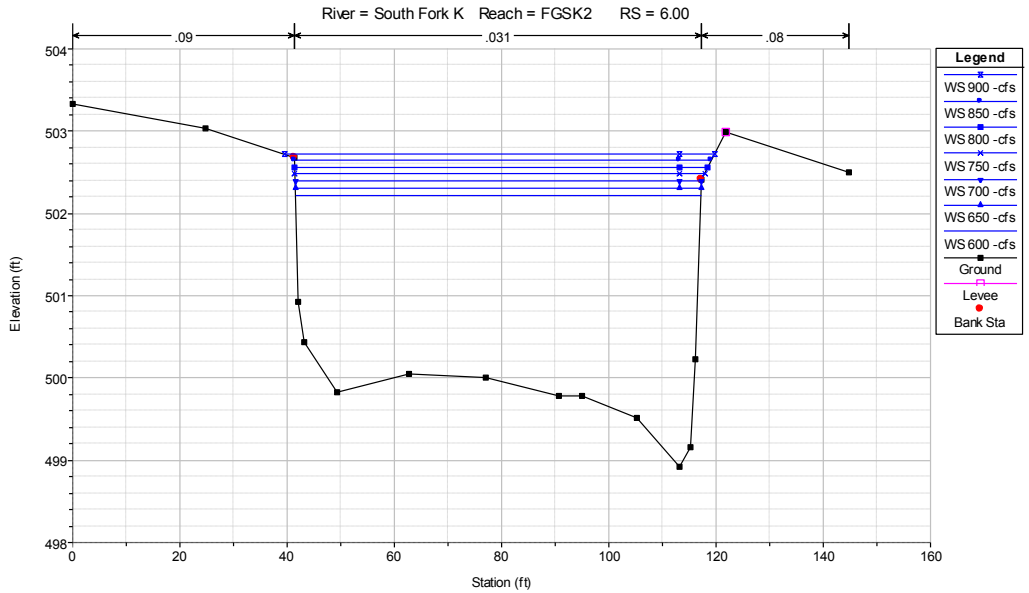

Figure 10 River Station (RS) 6 on River Reach FGSK2. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK2

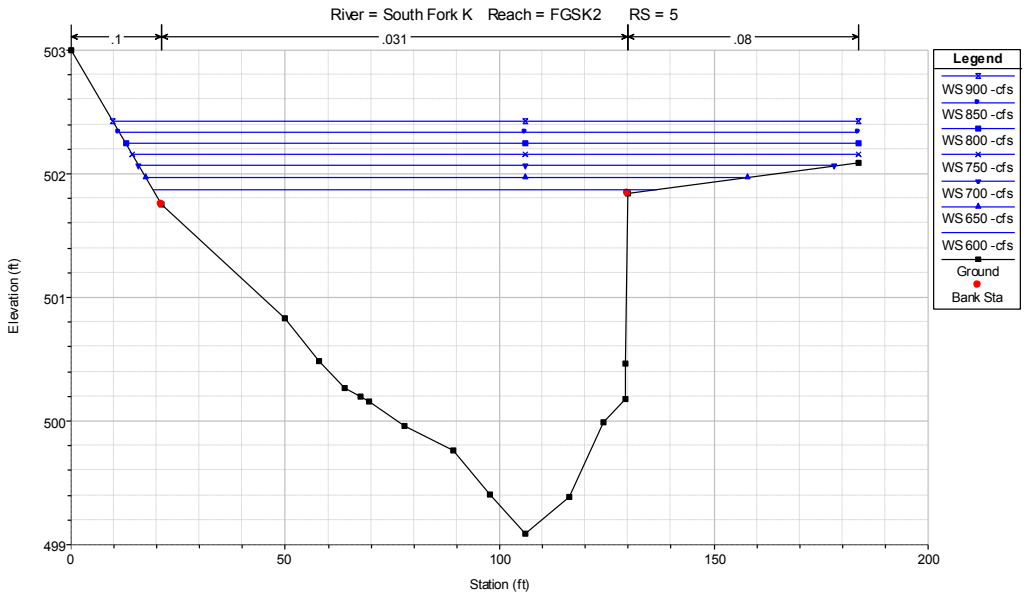

Figure 11 River Station (RS) 5 on River Reach FGSK2. The black line represents the channel ground, facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK2

Site Characteristics.

Site Name	**FGSK3**		
Discharge (cfs)	**625 (550-850)**	Width (ft)	**49.5 (46.4-53.0)**
Slope	**0.0014**	Cross-sectional Area (ft^2)	**171 (150-190)**
(1) D_{50}	**27**	D_{84}	**48**
(2) D_{50}	**36**	D_{84}	**70**
Lat/Long Location	**N59.80290 W155.69198**	Drainage Area (mi^2)	**89**
% Willow	**30**		
% Grass	**60**		
% Tree	**0**		

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 430 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 6 and 5 characterize a riffle and serve as the reference reach. Sections 5 through 1 characterize the downstream pool. Pebble count 1 was taken at River Station (RS) 6 while pebble count 2 was taken just upstream of Section 5 through the lower 20% of the riffle. Pebble count 1's distribution is tighter than those sampled from the surrounding sites (FGSK4, 5 and 7) and observations were made that the sampled area included recent fish spawning activity. Pebble count 2's distribution is wider and more similar to those of the nearby sites. The following analysis is based on both distributions.

For a Shields number of 0.017, the D_{84} from pebble count 1 begins to move from Section 5 at 700 cfs and pebble count 2 at 625 cfs. The D_{84} from pebble count 2 is immobile at River Station 5. For a Shields number of 0.026 the D_{50} from pebble count 1 moves before 550 cfs on Section 6 and 600 cfs on Section 5. It is unclear as to why the incipient motion analysis corresponds well with the pebble count apparently influenced by recent fish spawning activity. There may be lag present in pebble count 2 that was unable to be accounted for as it is unclear within the distribution which particle sizes are immobile. However, these results match the geometry well notably on Section 6 where a discharge of 625 cfs overtops the left bank as well as matches the left floodplain elevation and right bank levee on Section 4.

The reference reach, which include riffle Sections 6 through 5, provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 480 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the downstream pool. At the downstream end of the reach a backwater channel with evidence of beaver activity enters along the left bank. Sections 1 and 2 required the addition of an ineffective flow boundary to account for the lack of conveyance during high flows. Sections 7 and 6 characterize a riffle which serves as the reference reach. The pebble count was taken along Section 6.

The incipient motion analysis through the riffle to the slipface of the pool (Sections 7 through 5) shows that for a Shields number of 0.017, the D_{84} does not move, even for the upper end of the range of flows (700 cfs). For a Shields number of 0.026, the D_{50} is also immobile through the riffle. These results may indicate the presence of lag in the pebble count that was unable to be accounted for as it is unclear within the distribution which particle sizes are immobile. However, the presence of two peaks in the pebble count may be indicative in the presence of some immobile material. Without a strong INCIPIENT MOTION ANALYSIS: , channel forming discharges were chosen based on channel geometry and field indicators. The right bank along the riffle is overtopped by 600 cfs on Section 7 and by 500 cfs on Section 6. A discharge of 600 cfs matches the geometry of Section 4 well.

The reference reach, which include riffle Sections 7 through 6, provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

	% Tree	**10**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 530 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and crest of the pool. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 8 through 4 characterize the reference reach which includes a riffle (Sections 8 to 7) and run (Sections 7 to 6). Sections 6 to 5 constitute a glide followed by a steep riffle (Sections 5 and 4). The pebble count was taken between Sections 7 and 8. A relic channel is evident along the left bank at Section 5 where a depositional bar has formed at this local widening. The ineffective flow option was used in the HEC-RAS model to account for the zone downstream of the bar which ponds water but does not contribute to conveyance area. Sections 4 through 1 characterize the pool.

For a Shields number of 0.017, the D_{84} moves from Section 8 between 550 and 575 cfs, between 650 and 700 cfs on Section 6 and between 575 and 600 cfs on Section 4. For a Shields number of 0.026, the D_{50} moves from Section 7 by 500 cfs, Section 5 at 550 cfs and before 500 cfs on the rest of the sections within the reference reach. The channel geometry and field indicators match discharges between 650 and 750 cfs well matching inflection points and floodplain elevations through the reference reach.

The reference reach sections (Sections 8 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGSK5

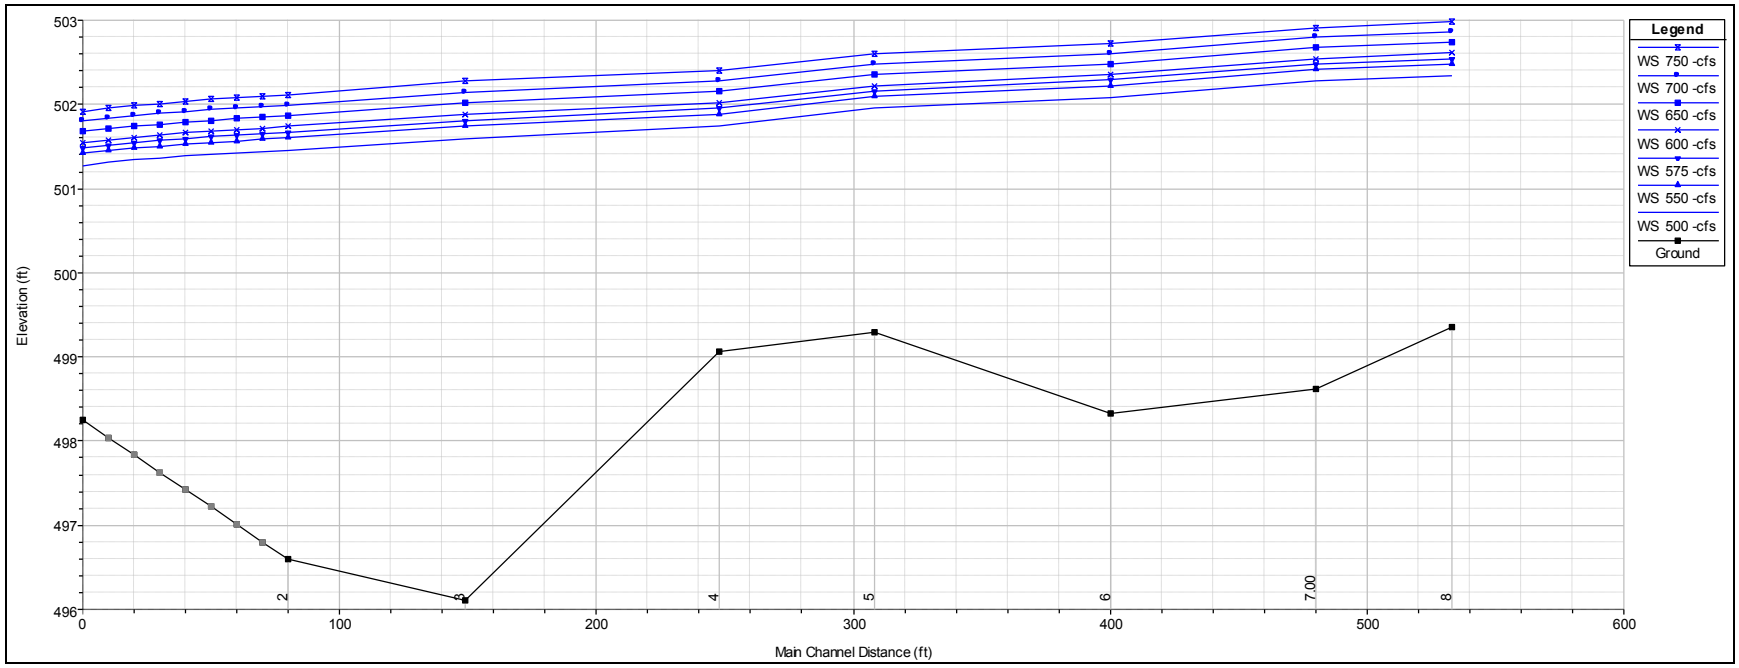

Figure 30 HEC-RAS longitudinal profile output for Reach FGSK5. Numbers 1-8 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK5

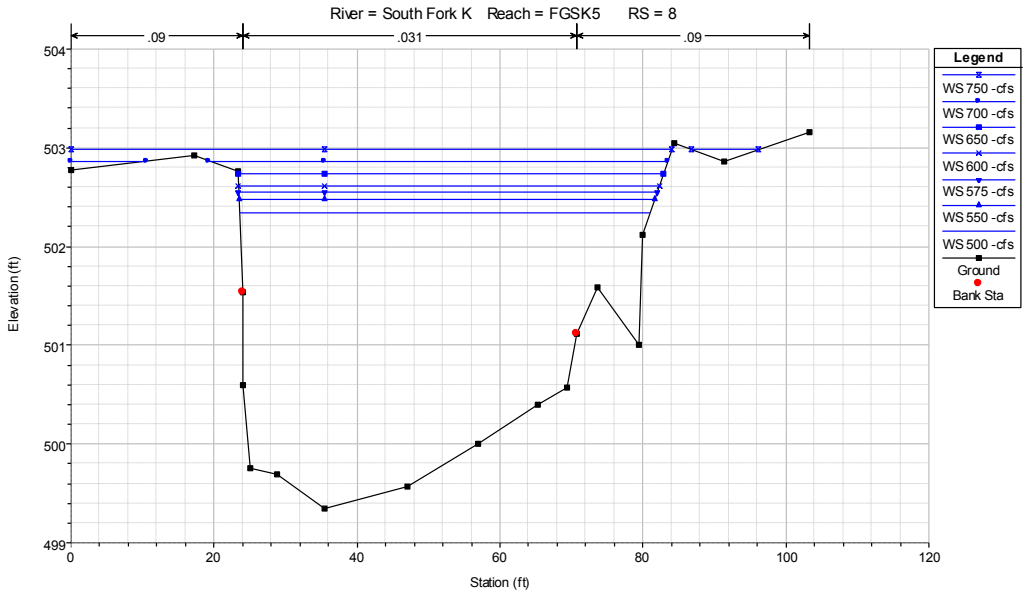

Figure 31 River Station (RS) 8 on River Reach FGSK5. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections over 575 feet of stream. Section 1 serves as the downstream hydraulic control for the pool. Sections 6 through 4 characterize a riffle. The pebble count was taken across River Station (RS) 5. Sections 1 through 4 capture a deep pool which has a noticeable amount of fines. The bed through the riffle was noted as fairly embedded and relatively plane bed, generally a depositional feature. The presence of moss along the channel bed was also noted at the time of the survey.

Due to FGSK6's location just upstream of a mature meander bend, the channel geometry is believed to be a result of a backwater environment. Due to this backwatering during channel forming discharges, water stacks up and finds alternate paths. One such path is apparent on the air photo along the left bank downstream of Section 1. Due to this complex hydraulic condition and its difficulty in capturing in a step-backwater model, FGSK6 was not analyzed further for incorporation into the regression data set.

Site Overview. While not incorporated into the hydraulic model, the HDR hydrology gage SK100B is located close enough to FGSK7 to provide an idea of the frequency and magnitude of discharge events (see attached HYDROGRAPH:) and calibrate the hydraulic model. This site was resurveyed during Inter-Fluve, Inc.'s September 2007 field efforts which happened to coincide with a high flow event (~445 cfs on 9/8/2007). Water surface elevations at each section were used to calibrate the roughness through the model. A channel roughness Manning's n value of 0.029 most closely matched the surveyed water surface elevations for a discharge of 445 cfs.

During Inter-Fluve, Inc.'s field efforts in September 2007, field personnel surveyed nine cross-sections along 815' of channel length. Section 1 serves as the downstream hydraulic control for the model. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Cross Sections 7 through 9 represent a pool/glide at the bottom of a riffle. Section 7 characterizes the pool crest and the beginning of the next pool/glide which is characterized by Sections 7 through 4. Cross-sections 4 through 1 characterize a steeper glide. The pebble count and bulk sample were taken around cross-Section 7.

According to the hydrograph , channel forming discharges most likely fall between 600 and 800 cfs based on the frequency and duration of events. The incipient motion analysis , based on average boundary shear, concludes that the D_{84} does not move through this reach at a Shields number of 0.017. Mobility for the range of Shields numbers used more closely resembles the D_{50} Sampled across River Stations (RS) 7 and 6. Observations by HDR personnel on site during high flows note seeing strips of bedload movement. This might suggest that a portion of the bed is immobile or lag material. Therefore, there may be lag present in the pebble count that was unable to be accounted for as it is unclear within the distribution

SITE DESCRIPTION: FGSK7

which particle sizes are immobile. Discharges between 550 and 800 cfs match most inflection points through the reach and specifically a discharge of 650 cfs matches inflection points on Sections 8 through 5.

Due to the lack of a well-defined riffle and the relative homogeneity within the reach, all surveyed cross-sections (with the exception of Section 1 as it serves as the downstream boundary) were used to find average channel width and cross-sectional area over the range of flows.

% Willow		**50**	
% Grass		**50**	
% Tree		**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 460 feet of channel length. Section 1 serves as the temporary downstream hydraulic control for the model and represents the crest of the pool. Sections 8 through 4 represent the reference reach which include a glide (Sections 8 through 7) and a riffle (Sections 7 through 5). The pebble count was taken between Sections 6 and 5. Sections 4 through 1 characterize the downstream pool. While not incorporated into the hydraulic model, the HDR hydrology gage SK100B1 is located close enough to FGSK8 to provide an idea of the frequency and magnitude of discharge events (see attached hydrograph).

In general there is good agreement between the incipient motion analysis Sampled across River Stations (RS) 6 and 5 and the geometry and channel-forming indicators found through the reach. For a Shields number of 0.017 the D_{84} begins to move between 425 and 550 cfs. A discharge of 525 cfs matches the left bank on Section 8, the right top of bank on Sections 6 and 4, and the top of the gravel bar through the pool (Sections 3 through 1).

The reference reach, which includes a riffle and the upstream run/glide (Sections 8 through 4), provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGSK8

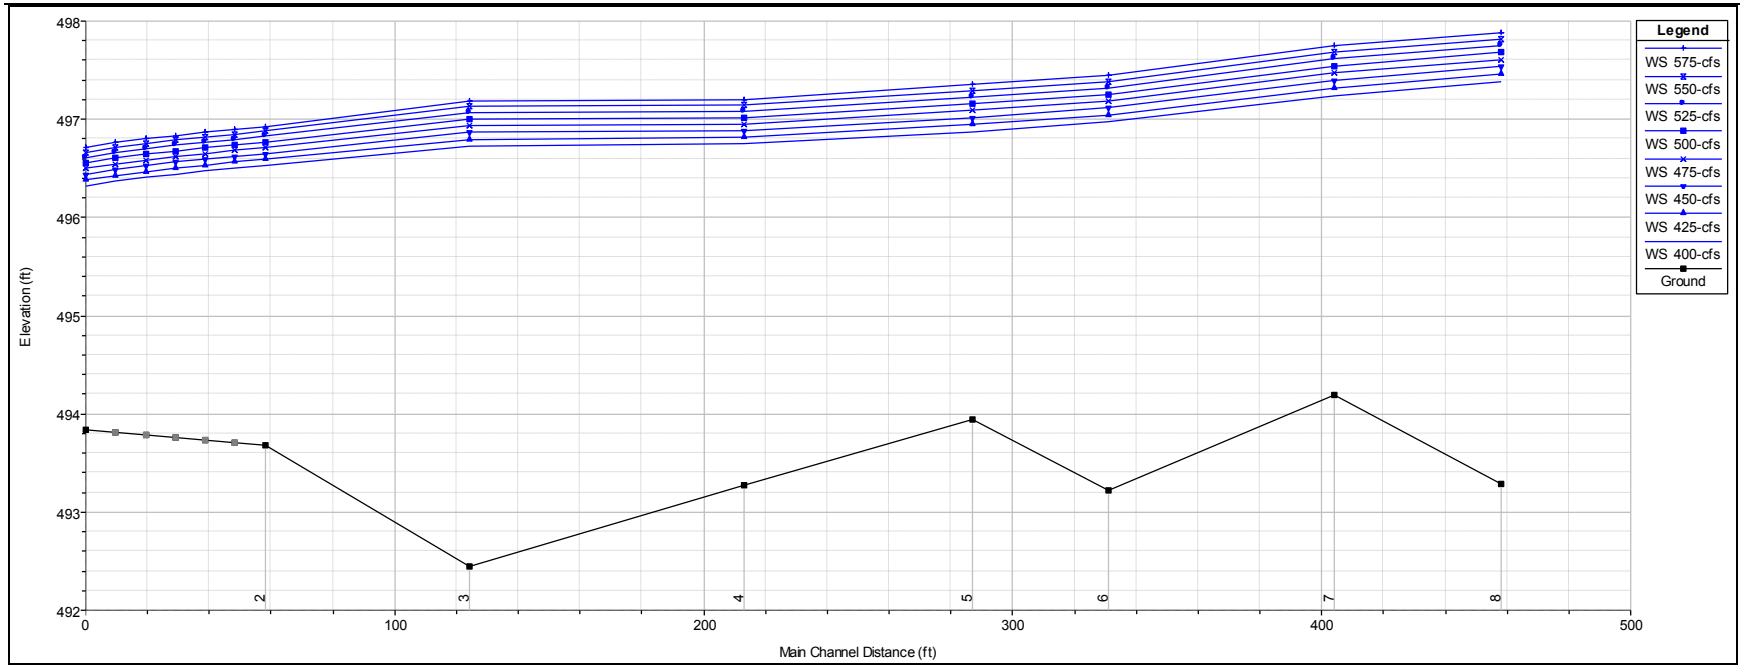

Figure 50 HEC-RAS longitudinal profile output for Reach FGSK8. Numbers 1-8 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK8

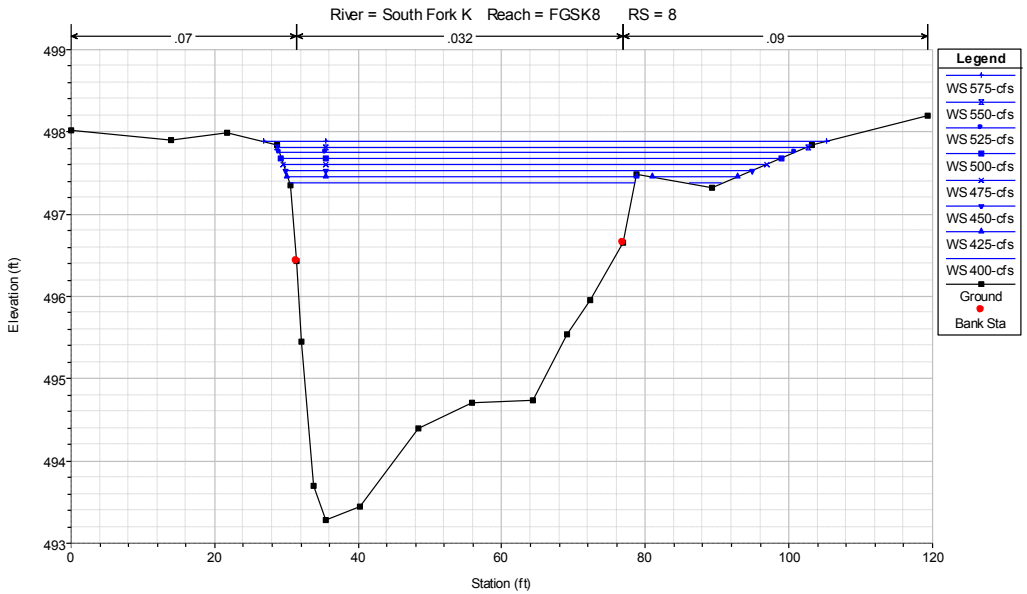

Figure 51 River Station (RS) 8 on River Reach FGSK8. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

SITE DESCRIPTION: FGSK9

Site Characteristics.

Site Name		**FGSK9**	
Discharge (cfs)	**450 (325-500)**	Width (ft)	**45.8 (35.7-51.9)**
Slope	**0.0020**	Cross-sectional Area (ft^2)	**128 (90-176)**
D_{50}	**36**	D_{84}	**70**
Lat/Long Location	**N59.81525 W155.43006**	Drainage Area (mi^2)	**50**
% Willow		**85**	
% Grass		**15**	
% Tree		**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 360 feet of channel length. Section 1 serves as the temporary downstream hydraulic control for the model and represents the crest of the downstream pool. Lacking any well-formed riffles, the crest of a pool/glide (Section 5) served as the reference section and pebble count location. Upwelling from the bed was observed in this reach. Large mats of moss covered around 65% of the channel bottom (see photo) increasing the roughness of the channel. Manning's n was increased to 0.035. Portions of the bed not covered by moss were extremely loose.

The incipient motion analysis shows that for a Shields number of 0.017, the D_{84} moves between 425 and 450 cfs on Section 6. The D_{84}'s mobility through the rest of the site is variable, ranging from greater than 500 cfs to less than 325 cfs. For a Shields number of 0.026, the D_{50} moves at 325 cfs on Section 6 and 450 cfs on Section 5. The potential affect of the moss on the mobility of the bed is unknown and therefore has not been taken into account in the incipient motion analysis. A target flow of 450 cfs matches the geometry well on Section 6 where it hits an inflection point on the right bank and Section 4 where it just overtops the gravel bar along the right bank.

Lacking a well-defined riffle, channel width and cross-sectional area were averaged across Sections 7 through 3 for the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGSK9

HEC-RAS LONGITUDINAL PROFILE: FGSK9

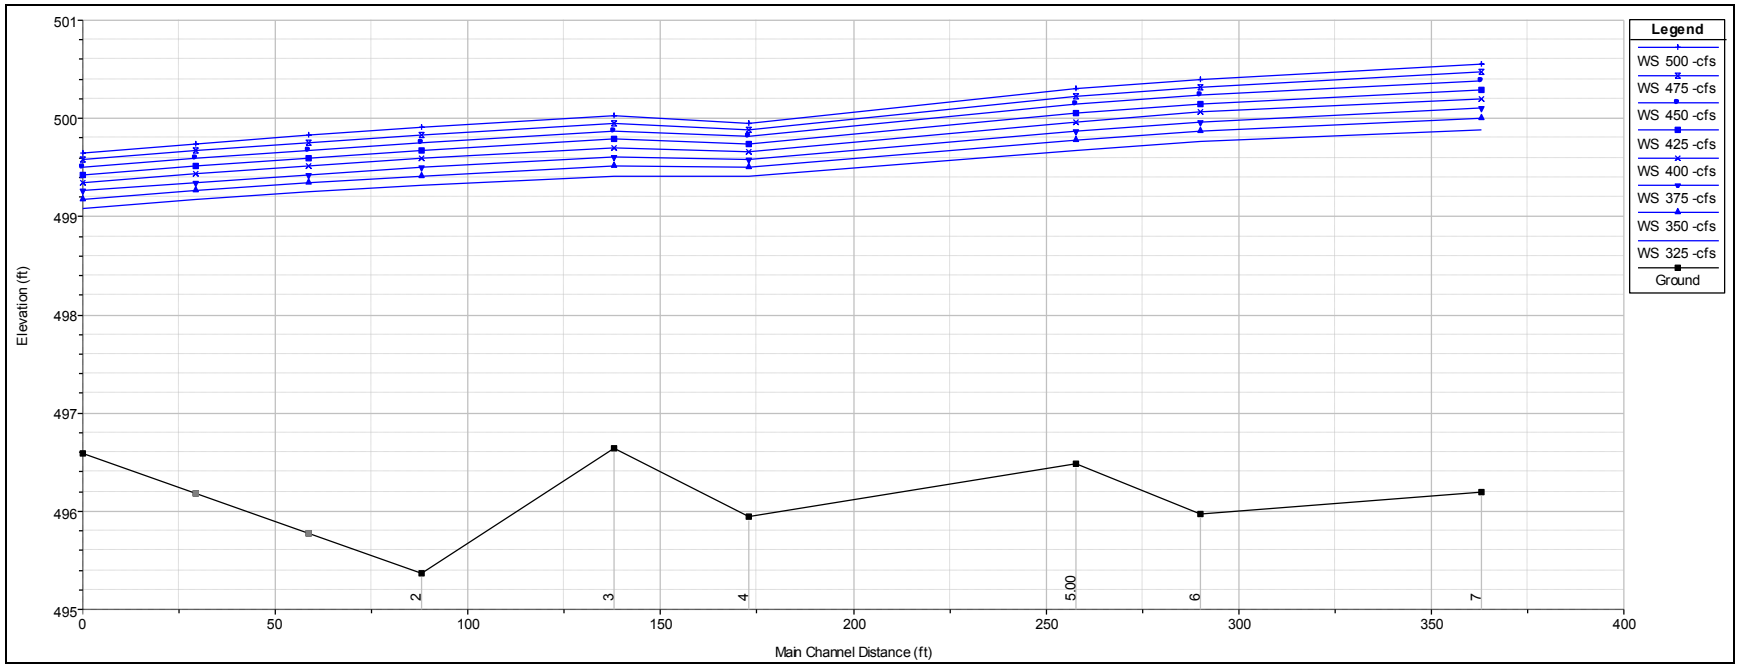

Figure 60 HEC-RAS longitudinal profile output for Reach FGSK9. Numbers 1-7 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK9

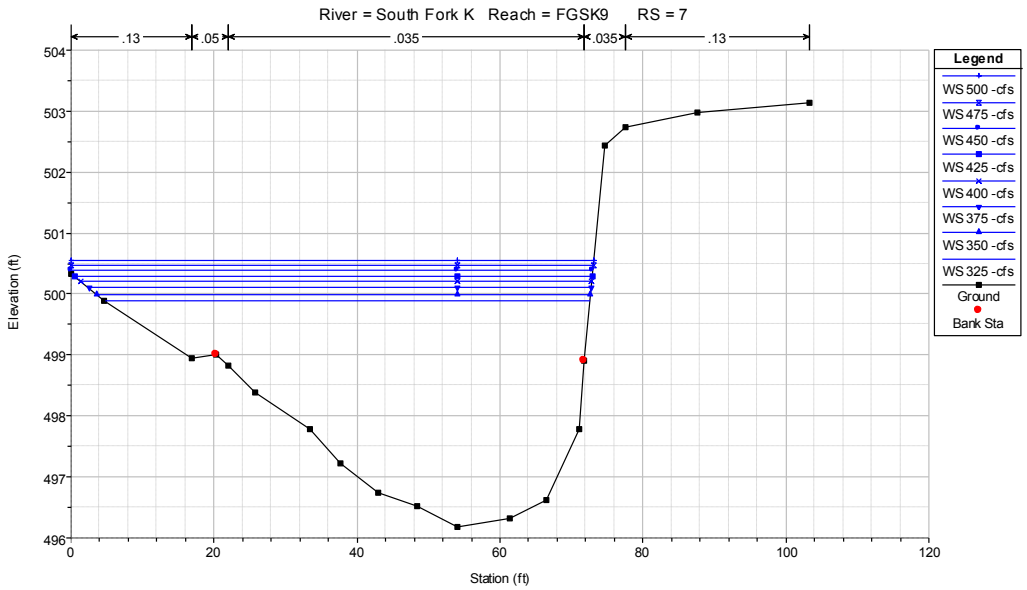

Figure 61 River Station (RS) 7 on River Reach FGSK9. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 300 feet of channel length. Section 1 serves as the temporary downstream hydraulic control for the model. At the time of the survey, the channel was completely dry. Therefore, for this site, the DEM-derived reach-average slope was used as the suitable boundary condition. Sections 6 through 4 characterize the riffle which serves as the reference reach. The pebble count was taken sampled across River Station (RS) 5. Sections 8 through 6 captured the pool upstream. An HDR surface water gage (SK100C) sits between Sections 8 and 7 within the pool. Below the riffle, Sections 4 through 2 characterize another pool. Large gravels on the bed, absent of fines underlain by sand and small gravels suggest a classic armor layer (see photos). Tributary SK119 enters the South Fork Koktuli below this site.

A preliminary rating curve formulated by Knight-Piesold and based on the instantaneous discharge measurements collected by HDR was provided to IFI by HDR on 2/11/2008. Incorporation of the cross-section taken by HDR through the gage into the FGSK10 hydraulic model allowed for the calibration of Manning's channel roughness based on the stage discharge relationship defined by the rating curve (See Attachment 1 for details). Based on the results of this exercise, channel roughness for the flows of interest are roughly equal 0.040. Additionally, HDR provided a rating two years of hydrology (07/04 - 06/06) from SK100C which were used to as a check on the frequency and magnitude of the range of flows chosen.

For a Shields number of 0.017, the D_{84} moves between 325 and 350 cfs, but does not move within the range of flows at any of the other cross-sections. For a Shields number of 0.026, the D_{50} moves by 250 cfs on Section 6 and 400 cfs on Section 5. While the geometry through most of the reach suggest flows on the lower end of the range, the incipient motion analysis and a reference to "top of bank" being matched for a flow around 340 cfs on the rating curve (see below), provides confidence in the nominal value and range.

SITE DESCRIPTION: FGSK10

The reference reach sections (Sections 6 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 470 feet of channel length. Lacking well-defined bedforms, cross-sections were chosen based on planform and bank conditions. Silt and clay covered the bed with extremely small deposits of sand and small gravels locally exposed. A pebble count was performed across one such section (Section 5). Since no hydraulic controls exist within this reach, the downstream-most section was determined based on distance from the pebble count section. The channel banks were tall and irregular due to frequent failure, composed of fines and covered with tall grass.

The incipient motion analysis showed that at a flow of 250 cfs, for a Shields number of 0.017, particles of 13 mm or less would be mobile. The geometry through the reach was fairly consistent. The range of flows chosen hit inflection points along all sections along both banks. Notably 250 cfs matches inflection points on Sections 5, 4, and 2.

Without a well-defined riffle, channel width and cross-sectional area were averaged across surveyed cross-Sections 6 through 2 for the range of flows.

SITE DESCRIPTION: FGSK12

Site Characteristics.

	Site Name	**FGSK12**	
Discharge (cfs)	**280 (240-340)**	Width (ft)	**29.4 (24.8-37.4)**
Slope	**0.0007**	Cross-sectional Area (ft^2)	**127 (98-162)**
D_{50}	**11**	D_{84}	**21**
Lat/Long Location	**N59.81406 W155.35215**	Drainage Area (mi^2)	**30**
	% Willow	**0**	
	% Grass	**100**	
	% Tree	**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 415 feet of channel length. Section 1 serves as the downstream control for the hydraulic model and is the crest of the downstream pool. Consisting mostly of pools, a pebble count was taken along a short riffle/pool crest (Sections 5 and 6). Pools were covered with fines while the pool crests and gravel bars had sand and small gravels. The channel banks were tall and irregular due to frequent failure, composed of fines and covered with tall grass.

For a Shields number of 0.017, the D_{84} moves in the reference reach (Sections 6 and 5) at a flow of 280 and 240 cfs respectively and moves through the pools at flows lower than the range of flows reported here. Flows between 260 and 300 cfs match the right bank in the reference reach. The right bank along Sections 3 and 4 (the inner bend) are overtopped at flows above 240 cfs.

Without a well-defined riffle, channel width and cross-sectional area were averaged across surveyed cross-Sections 6 through 2 for the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGSK12

SITE DESCRIPTION: FGSK13

Site Characteristics.

Site Name	**FGSK13**		
Discharge (cfs)	**175 (125-325)**	Width (ft)	**23.7 (19.0-29.6)**
Slope	**0.0021**	Cross-sectional Area (ft^2)	**65 (37-111)**
D_{50}	**16**	D_{84}	**30**
Lat/Long Location	**N59.81901 W155.33682**	Drainage Area (mi^2)	**17**
% Willow	**20**		
% Grass	**80**		
% Tree	**0**		

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 355 feet of channel length. Section 1 serves as the downstream control for the hydraulic model and is the crest of the downstream pool. Consisting mostly of pools, a pebble count was taken along a short riffle/pool crest (Sections 5 and 6). This feature serves as the reference reach. Pools were covered with fines while the pool crests and gravel bars had sand and small gravels. The channel banks were tall and irregular due to frequent failure, composed of fines and covered with tall grass with few willows.

The incipient motion analysis shows a great deal of variability between sections ranging in competency for a Shields number of 0.017 from around 130 mm particle along Section 6 (the slip face of a riffle) to 22 mm in Section 4 (a scour pool which is most likely backwatered during high flows). For a Shields number of 0.017, the D_{84} moves in the reference reach (Sections 6 and 5) by 125 cfs. A flow of 200 cfs matches the geometry well of Sections 8, 6 and 2. The range of flows chosen for this site is large, encompassing the range in geometry found through the reach.

Without a well-defined riffle and high variability through the reach, channel width and cross-sectional area were averaged across surveyed cross-Sections 6 through 2 for the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGSK13

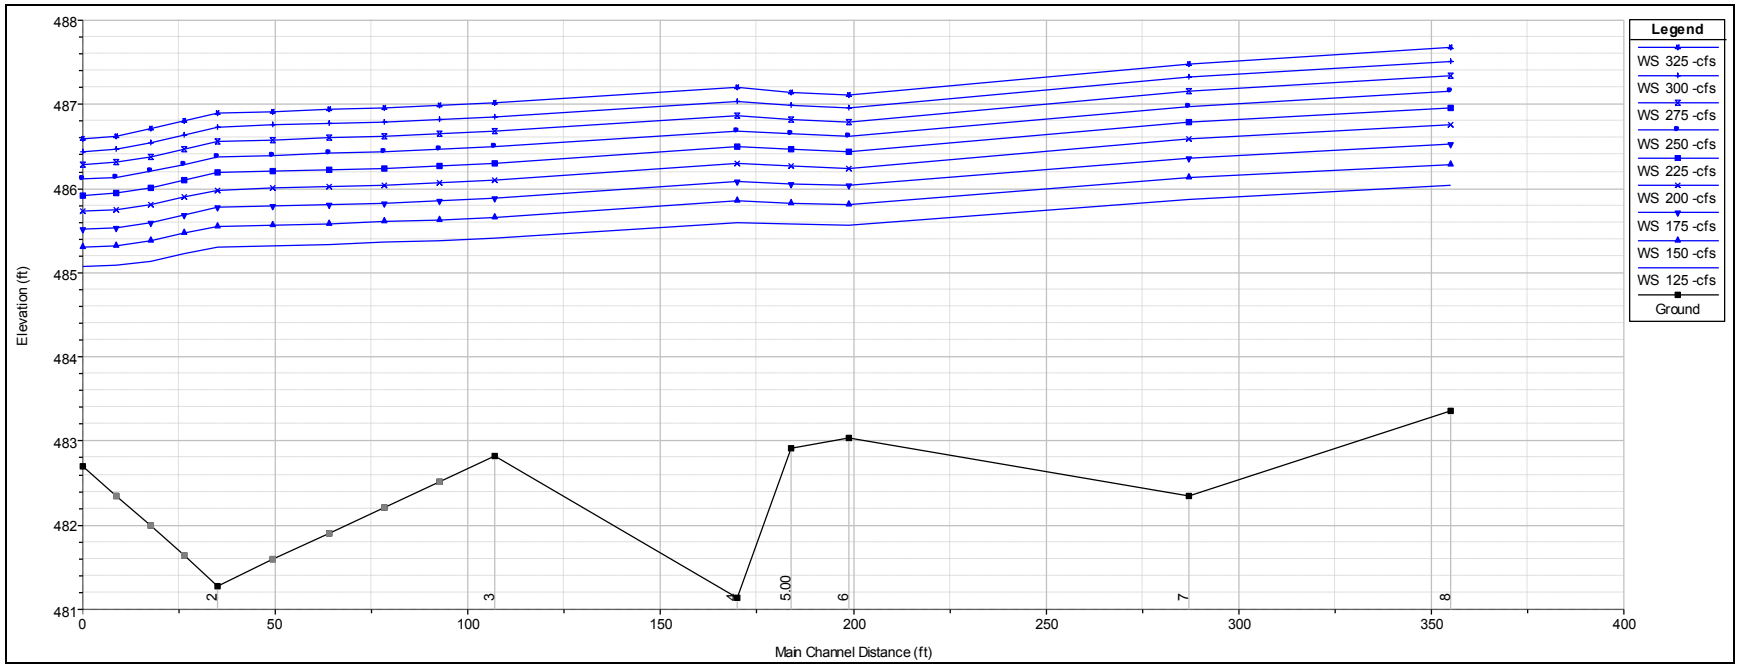

Figure 93 HEC-RAS longitudinal profile output for Reach FGSK12. Numbers 1-8 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK13

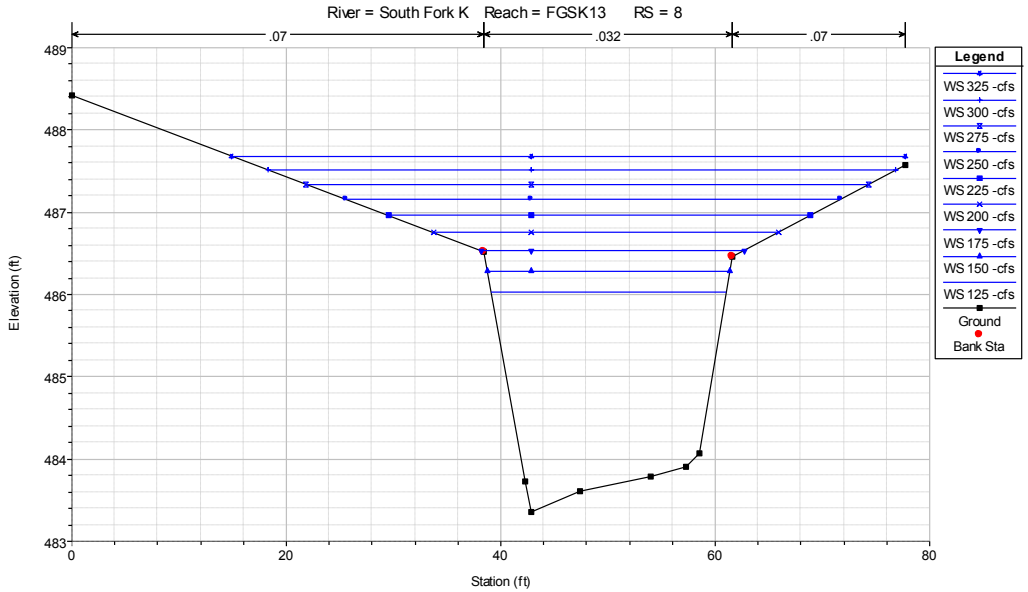

Figure 94 River Station (RS) 8 on River Reach FGSK13. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK13

SITE DESCRIPTION: FGSK14

Site Characteristics.

	Site Name	**FGSK14**	
Discharge (cfs)	**150 (100-200)**	Width (ft)	**23.7 (16.9-32.2)**
Slope	**0.0060**	Cross-sectional Area (ft^2)	**42 (22-71)**
D_{50}	**26**	D_{84}	**93**
(modified) D_{50}	**31**	D_{84}	**102**
Lat/Long Location	**N59.81899 W155.29575**	Drainage Area (mi^2)	**16**
	% Willow	**35**	
	% Grass	**65**	
	% Tree	**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 355 feet of channel length. Section 1 serves as the downstream control for the hydraulic model and is the crest of the downstream pool. Consisting mostly of pools, a pebble count was taken along a short riffle/pool crest (Section 5). This feature served as the reference reach. Substrate changed from fines in the pools to cobbles and gravels at the crests and along the bars. An abundance of fines (< 2 mm) in the pebble count along with a wide distribution may indicate a falling limb signature. To account for this, the distribution was modified by removing the < 2 mm size class. Both the original data as well as the modified distribution are included. Channel banks were composed of silts with mostly grass and some willows.

For a Shields number of 0.017, the D_{84} of the modified pebble count (102 mm) moves through the upper cross-sections (7 through 5) at flows between 100 and 150 cfs. Below that, the range at which mobility takes place greatly varies and may be a function of the variability of bed-forms and bank conditions. There is not good agreement between the incipient motion analysis and the geometry. Flows between 100 and 150 cfs remain well within the banks for all of the sections. These flows do match a bench along the left bank of Section 4. Lacking strong geomorphic indicators due to potential ice and snow effects on the geometry of this reach, the flows chosen based on the incipient motion analysis along the top three Sections (7 through 5).

Without a well-defined riffle and high variability through the reach, channel width and cross-sectional area were averaged across surveyed cross Sections 6 through 2 for the range of flows.

HEC-RAS OUPUT SUMMARY TABLE: FGSK14

HEC-RAS LONGITUDINAL PROFILE: FGSK14

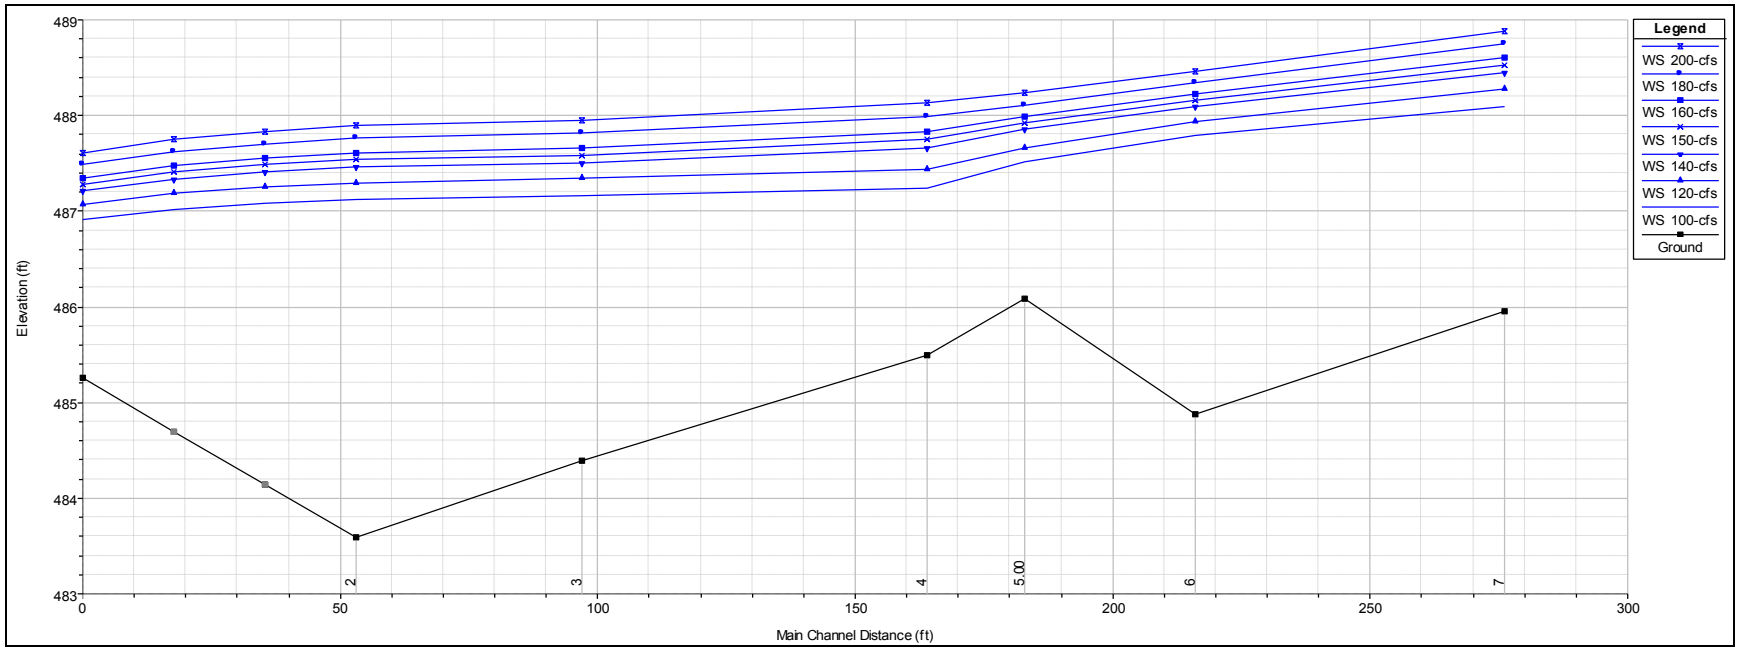

Figure 102 HEC-RAS longitudinal profile output for Reach FGSK14. Numbers 1-7 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGSK14

SITE DESCRIPTION: FGSK15

Site Characteristics.

Site Name	**FGSK15**		
Discharge (cfs)	**175 (125-225)**	Width (ft)	**23.3 (17.9-27.3)**
Slope	**0.0024**	Cross-sectional Area (ft^2)	**64 (44-88)**
D_{50}	**26**	D_{84}	**83**
Lat/Long Location	**N59.82555 W155.27640**	Drainage Area (mi^2)	**15**
% Willow	**50**		
% Grass	**50**		
% Tree	**0**		

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 260 feet of channel length. Cross-section 1 serves as the downstream control for the hydraulic model and is the crest of the small pool (Section 3 through 1). Sections 3 through 5 characterize the riffle which serves as the reference reach and the upstream Sections (5 through 7) represent a more well-defined pool. The current bedforms along the lower part of this reach are not-well formed, composed of loose gravels on top of a solid clay layer (possible evidence of past beaver activity), suggesting that a wave of sediment moves from River Station 5 through 1 having possibly been eroded from the adjacent banks. The pebble count was taken along Section 4.

For a Shields number of 0.017, the D_{84} moves between at 175 cfs along Section 4, but does not move from any of the other sections in the reference reach. The geometry of the left bank along Sections 5 through 2 matches flows of 175-225 cfs. The right bank of Section 6 matches 175 cfs

Without a well-defined riffle and high variability through the reach, channel width and cross-sectional area were averaged across surveyed cross-Sections 7 through 2 for the range of flows.

	% Willow	**50**	
	% Grass	**50**	
	% Tree	**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 240 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 7 through 5 characterize a riffle which serves as the reference reach. Sections 3 through 1 characterize the downstream pool. The pebble count was taken sampled across River Station (RS) 6. The broad distribution of the pebble count may suggest lag through this site. A discernable peak in the < 32 mm size class may suggest that the mobile D_{84} is closer to the 32 to 45 mm range.

The incipient motion analysis supports this observation. For a Shields number of 0.017, the D_{84} from the pebble count does not move through the reference reach (Sections 7 through 5) but does move by 105 cfs on Sections 4 and 2. However, for a Shields number of 0.017 at flow of 100 cfs, an average particle size of 35 mm moves through the reference reach. Flows between 90 and 105 cfs match inflection points through the reference reach. The top of the gravel bar along the left bank of Section 2 is matched by a flow of 105 cfs and overtopped thereafter.

The reference riffle sections (Sections 5 through 7) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGSK16

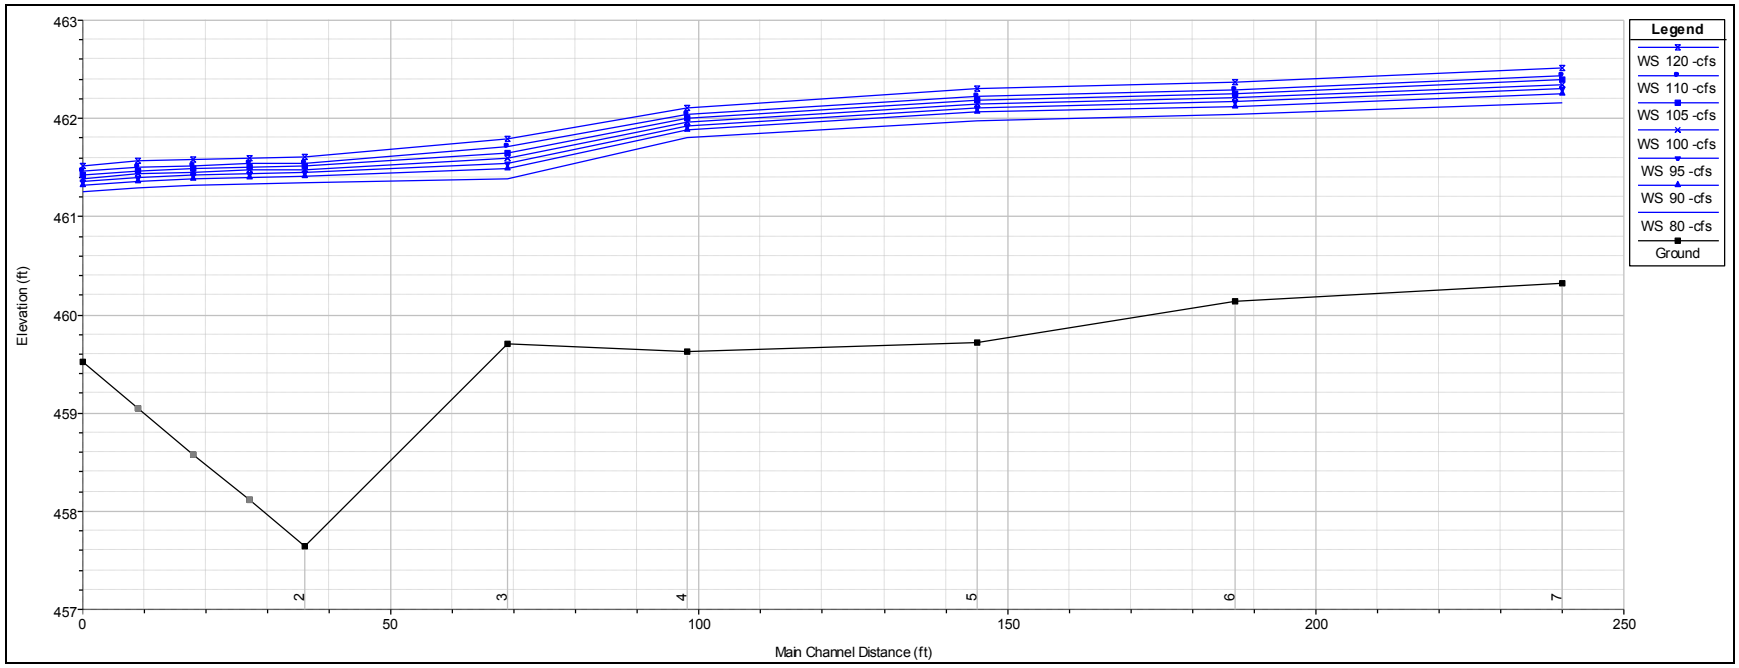

Figure 118 HEC-RAS longitudinal profile output for Reach FGSK16. Numbers 1-7 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK16

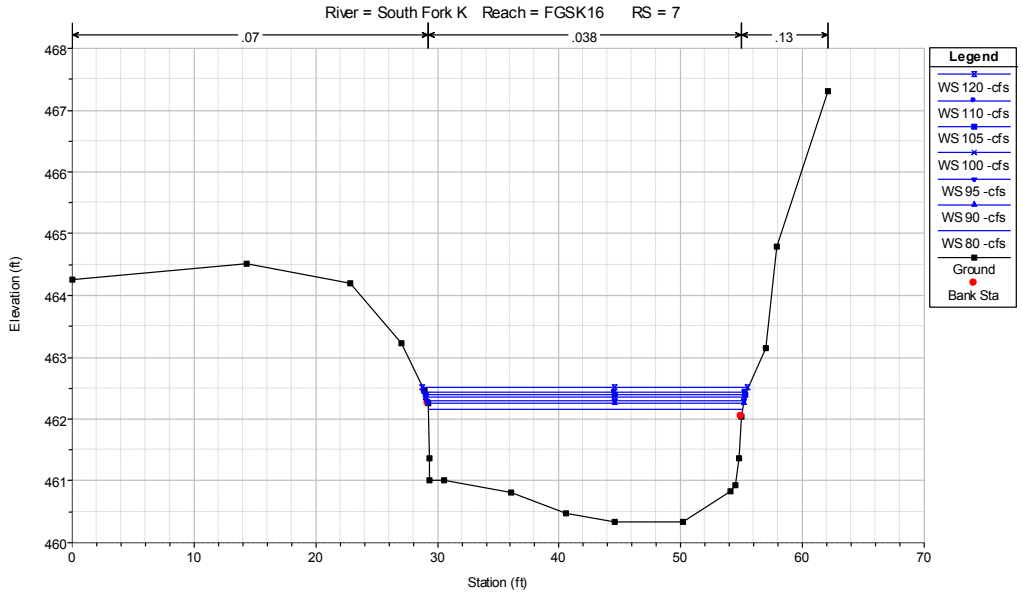

Figure 119 River Station (RS) 7 on River Reach FGSK16. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK16

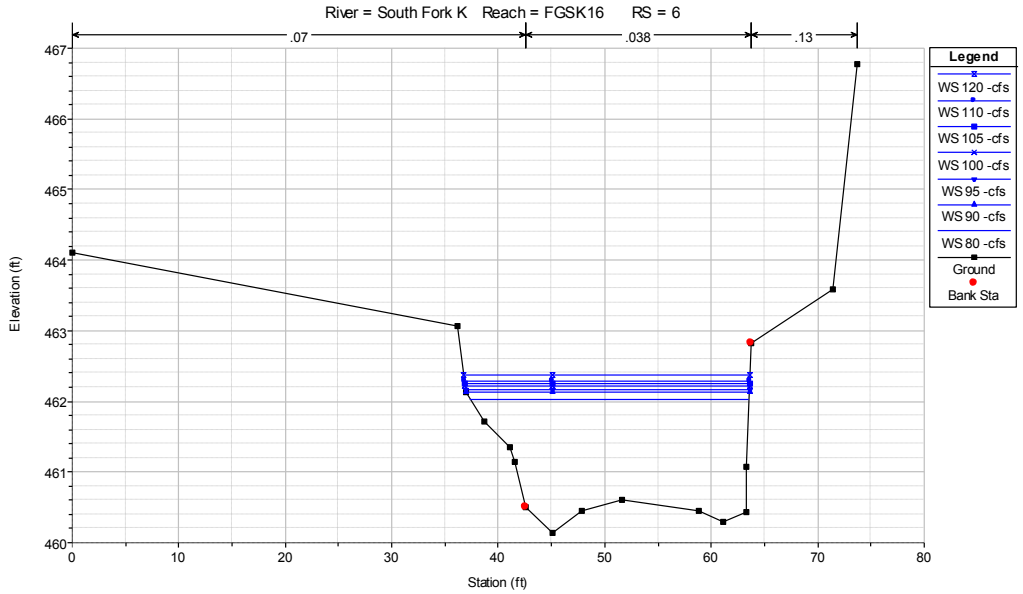

Figure 120 River Station (RS) 6 on River Reach FGSK16. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK16

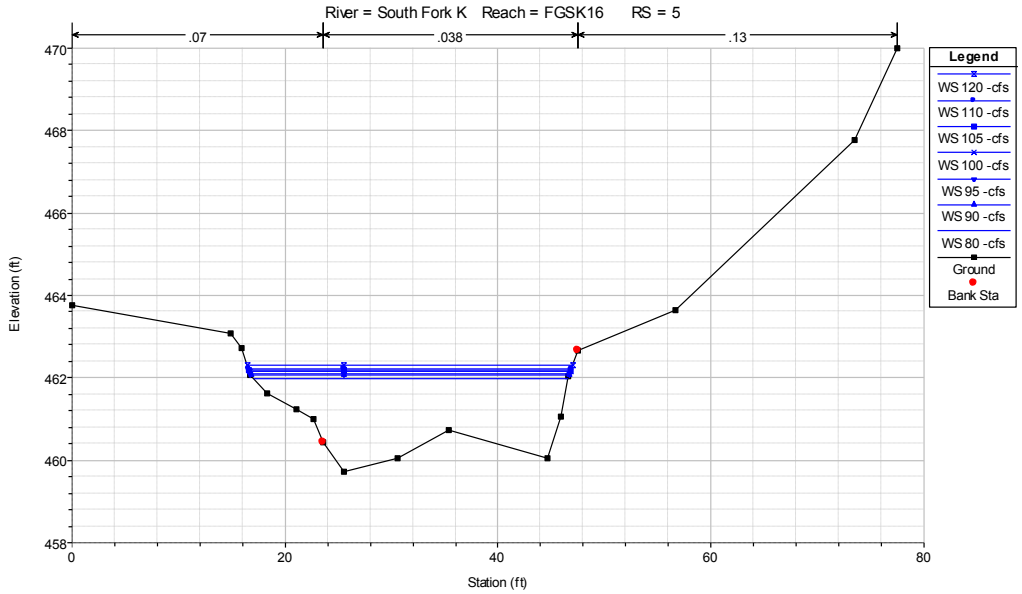

Figure 121 River Station (RS) 5 on River Reach FGSK16. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS SECTIONS: FGSK16

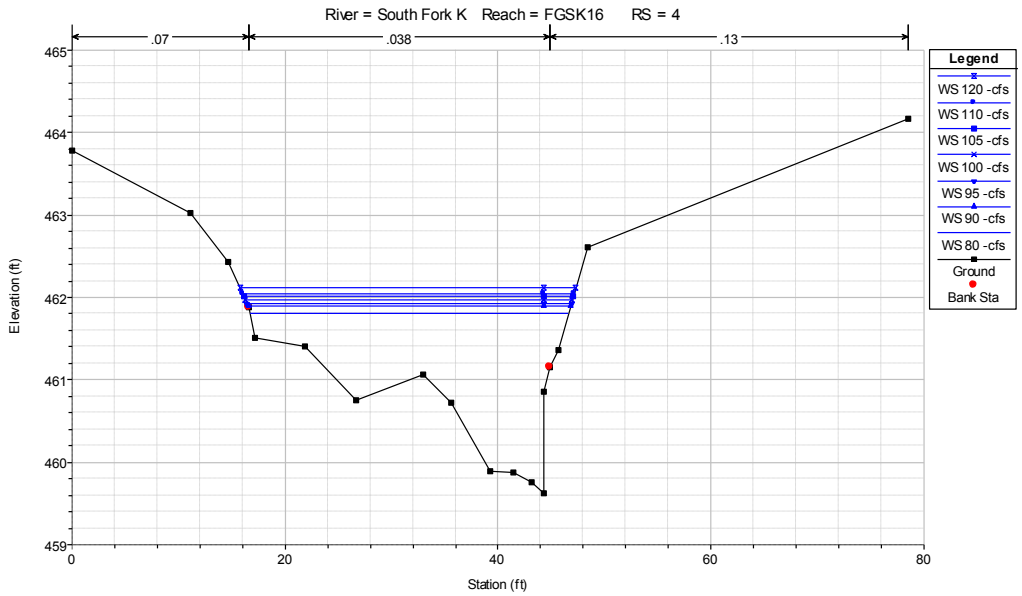

Figure 122 River Station (RS) 4 on River Reach FGSK16. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

SITE DESCRIPTION: FGSK119

Site Characteristics.

	Site Name	FGSK119	
Discharge (cfs)	**100 (75-125)**	Width (ft)	**30.9 (25.9-36.2)**
Slope	**0.0017**	Cross-sectional Area (ft^2)	**51 (37-67)**
D_{50}	**40**	D_{84}	**80**
Lat/Long Location	**N59.81674 W155.42369**	Drainage Area (mi^2)	**11**
	% Willow	**80**	
	% Grass	**20**	
	% Tree	**0**	

Site Overview. Located on the South Fork Koktuli tributary SK119, FGSK119 is close enough to the HDR gage SK119A to provide an idea of the frequency and magnitude of discharge events (see attached hydrograph). Upstream of this site, signatures of an old beaver dam since blown out exist. Coming in between FGSK10 and FGSK9, this site is a good indicator of the sediment and water introduced between these two sites. The geomorphology of FGSK119 may not be completely alluvial. Due to its position just upstream of the confluence on the upstream side of its valley, this site most likely has attributes of an alluvial fan and may have size fractions that only move during larger flows. The pebble count distribution graph exhibits a wide shoulder that could be indicative of lag deposits that are less mobile. If this were the case, the surface sample could be skewing D_{50} and D_{84} that are mobilized and responsible for existing channel dimensions. Gravel material in the bed was loose and exhibited signs of recent movement.

During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 170 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 6 through 4 characterize a riffle which serves as the reference reach. The pebble count was taken between Sections 6 and 5 while the bulk sample was taken between Sections 5 and 4. Sections 4 through 1 characterize the pool.

The incipient motion analysis shows no movement through the reference reach for either the D_{50} or D_{84}. The range of flows chosen based on geometry match the cross-sections well, hitting most inflection points and matching the lower portion of levees. Most notably 95-100 cfs matches the right bank on Sections 6 and 4 through the reference reach.

The reference reach sections (Sections 4 through 6) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

SITE DESCRIPTION: FGSKt-1

Site Characteristics.

Site Name		FGSKt-1	
Discharge (cfs)	**100 (80-120)**	Width (ft)	**38.9 (32.4-50.9)**
Slope	**0.0076**	Cross-sectional Area (ft^2)	**32 (26-41)**
D_{50}	**36**	D_{84}	**67**
Lat/Long Location	**N59.85534 W155.66553**	Drainage Area (mi^2)	**12**
	% Willow	**20**	
	% Grass	**80**	
	% Tree	**0**	

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 240 feet of channel length. Cross-section 1 serves as the downstream control for the hydraulic model and is the crest of the pool. Sections 6 through 4 characterize a riffle which serves as the reference reach. The pebble count was taken along Section 5. The presence of lag was noted in the pool, but was not apparent in the pebble count. FGSKt-1 is located on a tributary to the South Fork Koktuli that is suspected to be predominately controlled by groundwater-fed baseflow.

For a Shields number of 0.017, the D_{84} moves at River Station 5 at 100 cfs, before 80 cfs on Section 6 and is immobile within the range of flows on Section 4. For a Shields number of 0.026, the D_{50} moves before 80 cfs on Sections 6 and 5 but is immobile on Section 4. The geometry of the right bank through the reference reach was matched at flows between 90 and 120 cfs.

The reference reach sections (Sections 4 through 6) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGSKt-1

Reach	River Station	Profile	Discharge	Top Width	Area Channel	Hydraulic Depth	Max Depth	E.G. Slope	Velocity	Froude #	Shear	Weighted Manning's n

Site Overview. During Inter-Fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 150 feet of channel length. Cross-section 1 serves as the temporary hydraulic control as it the crest of the pool characterized by Sections 5 through 1. Downstream of this cross-section the channel takes a sharp turn. Wood was noted along the bed potentially providing grade control and oversteepening the channel through the bend. Sections 6 through 5 characterize a riffle through which the pebble count was taken. A surface water hydrology gage, SK124A was located in the pool between Sections 8 and 7.

Due to the sharp, oversteepend bend at the downstream boundary of FGSK124, the hydraulics through the site are difficult to model during high flows. Therefore, FGSK124 was not used in the regression analysis.

Site Overview. During Inter-fluve, Inc.'s field efforts in September 2007, field personnel surveyed seven cross-sections along 560 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 7 through 4 characterize the reference reach, which includes a glide (Sections 7 and 6) and a riffle (Sections 5 and 4). All four sections were included in the analysis because the presence of backwater areas along the left bank of Sections 5 and 4 were not completely representative of the channel geometry through the reach. A pebble count was taken through Section 4. A dry side channel was located on the right bank between Sections 2 and 4. Due to the roughness along the bank from the vegetation, the side channel was assumed to be ineffective during high flows and was not included in the hydraulic model.

For a Shields number of 0.017 the D_{84} moves between 1500 and 1600 cfs on the upper sections of the reach (Sections 6 and 7). Below that, incipient motion varies not moving through Section 5 at the lowest discharge in the range and moving through Section 4 by 1400 cfs. For a Shields number of 0.026, the D_{50} moves through Sections 7 through 4 by 1400 cfs. Throughout the reach the right bank inflection point matches discharges between 1450 and 1700 cfs. The left bank inflection point matches discharges around 1400 cfs.

The reference reach, including the riffle and glide sections (Sections 4 through 7), provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

Site Overview. During Inter-fluve, Inc.'s field efforts in September 2007, seven cross-sections were surveyed along 540 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 7 through 6 characterize the riffle which serves as the reference reach. The pebble count was taken through Section 6. A gravel bar located along the right bank of the pool (Sections 5 through 1) shows signs of bank formation (notably Section 1 and 2). The pebble count distribution is finer than that sampled at the upstream site (FGUTAPC2) and the downstream site (FGUT1).

For a Shields number of 0.017 the D_{84} moves at 1600 cfs and for a Shields number of 0.026 the D_{50} moves before 1100 cfs through Section 7. Along the rest of the cross-sections, the D_{84} moves before 1100 cfs (the lower end of the flow range). A discharge of 1500 cfs matches the geometry of the gravel bar along the lower portions of the pool (Sections 1 and 2) while 1700 cfs fully inundates the gravel bar surface.

The reference reach, which include the riffle sections (Sections 6 and 7), provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

Site Overview. During Inter-fluve, Inc.'s field efforts in September 2007, field personnel surveyed nine cross-sections along 960 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 6 through 4 characterize the riffle which serves as the reference reach. The pebble count was taken between Sections 5 and 4. An Alaska Peninsula Corporation gage (APC2) was located just upstream of Section 9. Sections 9 through 7 were included in order to incorporate this gage into the model once a rating curve is established. These sections are bedrock confined. Lag was noted in the field and suspected particle size classes were removed from the pebble count (see pebble count). A pebble count distribution may suggest the presence of greater amounts of lag than accounted for.

According to the incipient motion analysis, the D_{84} does not move through the reference reach within the range of channel forming discharges. For a Shields number of 0.026, the D_{50} moves through Section 6 and 5 by 1100 cfs. If the site does have unaccounted for lag, then these numbers would be in strong agreement with the geometry which shows 1150 cfs matching well with a right bank inflection point on Section 6 and 5.

The reference reach sections (Sections 6 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGUTAPC2

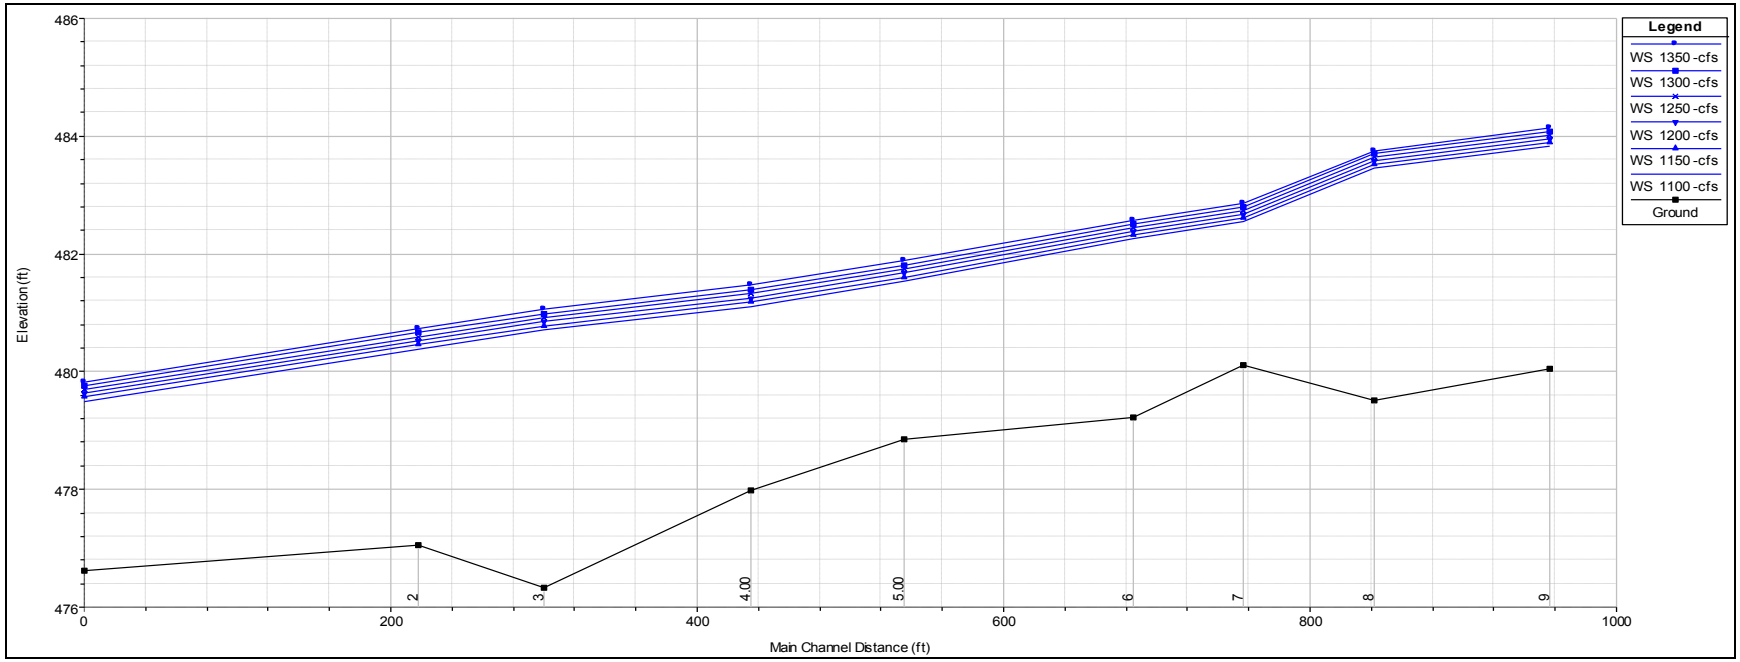

Figure 17 HEC-RAS longitudinal profile output for Reach FGUTAPC2. Numbers 1-9 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

			% Grass	**15**
			% Tree	**25**

Site Overview. During Inter-fluve, Inc.'s field efforts in September 2007, field personnel surveyed six cross-sections along 530 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 6 through 4 characterize the riffle which serves as the reference reach. Pebble count 1 was taken between Sections 5 and 4. Pebble count 2 was taken at the downstream boundary (Section 1), but was not used in the analysis due to its location on the downstream boundary. An Alaska Peninsula Corporation gage (APC1) was located between Sections 1 and 2.

The incipient motion analysis is in strong agreement with the geometry through the reference reach. For a Shields number of 0.017, the D_{84} moves through Section 4 at 1100 cfs and through Section 5 at 1250 cfs. The geometry of all three reference reach sections (6 through 4), matches 1150 cfs well.

The reference reach sections (Sections 6 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGUTAPC1

Site Overview. During Inter-fluve, Inc.'s field efforts in September 2007, field personnel surveyed 12 cross-sections along 890 feet of channel length. Sections 1 through 5 were disregarded for the analysis due to their difficulty to survey during high water conditions. This analysis relies on Sections 6 through 12. Section 6 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 12 through 10 characterize the riffle which serves as the reference reach. Pebble count 1 was taken between Sections 11 and 10. A second pebble count was conducted on the gravel bar adjacent to the pool (Sections 7 through 9). Coarse bed material through the riffle was thought to be immobile. Therefore, pebble count 1 was modified to account for this by removing those size classes which were thought to be lag. Both the original distribution as well as the modified one are included in the analysis.

For a Shields number of 0.017, the D_{84} of the modified distribution move through the reference sections (12 through 10) by 1050 cfs while the D_{84} for the unmodified distribution moves between 1100 and 1150 cfs. on Sections 12 and 10. For a Shields number of 0.026, the D_{50} moves at discharges below those included in the target range. These discharges match the geometry well. Lacking a well-defined bank along the right bank and a high terrace on the left bank, the assumption that flows overtopping the bar along the right bank 0.5'-1'above the surface are sufficient to establish these surfaces.

The reference reach sections (Sections 12 through 10) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGUT1.5

% Grass		**5**	
% Tree		**60**	

Site Overview. During Inter-fluve, Inc.'s field efforts in September 2007, field personnel surveyed six cross-sections along 580 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. A portion of the pool (Sections 3 and 2) was up against bedrock outcrop along the left bank. Sections 6 through 5 characterize the riffle which serves as the reference reach. The pebble count was taken between Sections 5 and 6. Coarse bed material through the riffle was thought to be immobile. Pebble count 1 was modified to account for this and both the original distribution as well as the modified one are included in the analysis.

For a Shields number of 0.017, the D_{84} of the modified distribution moves through Section 5 between 1050 and 1100 cfs. The D_{84}, however, does not move through Section 6. For a Shields number of 0.026, the D_{50} moves before 850 cfs on Sections 6 and 5. Discharges between 900 and 1000 cfs match the geometry of Sections 5 and 6 well.

The reference reach sections (Sections 6 and 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGUT1.6

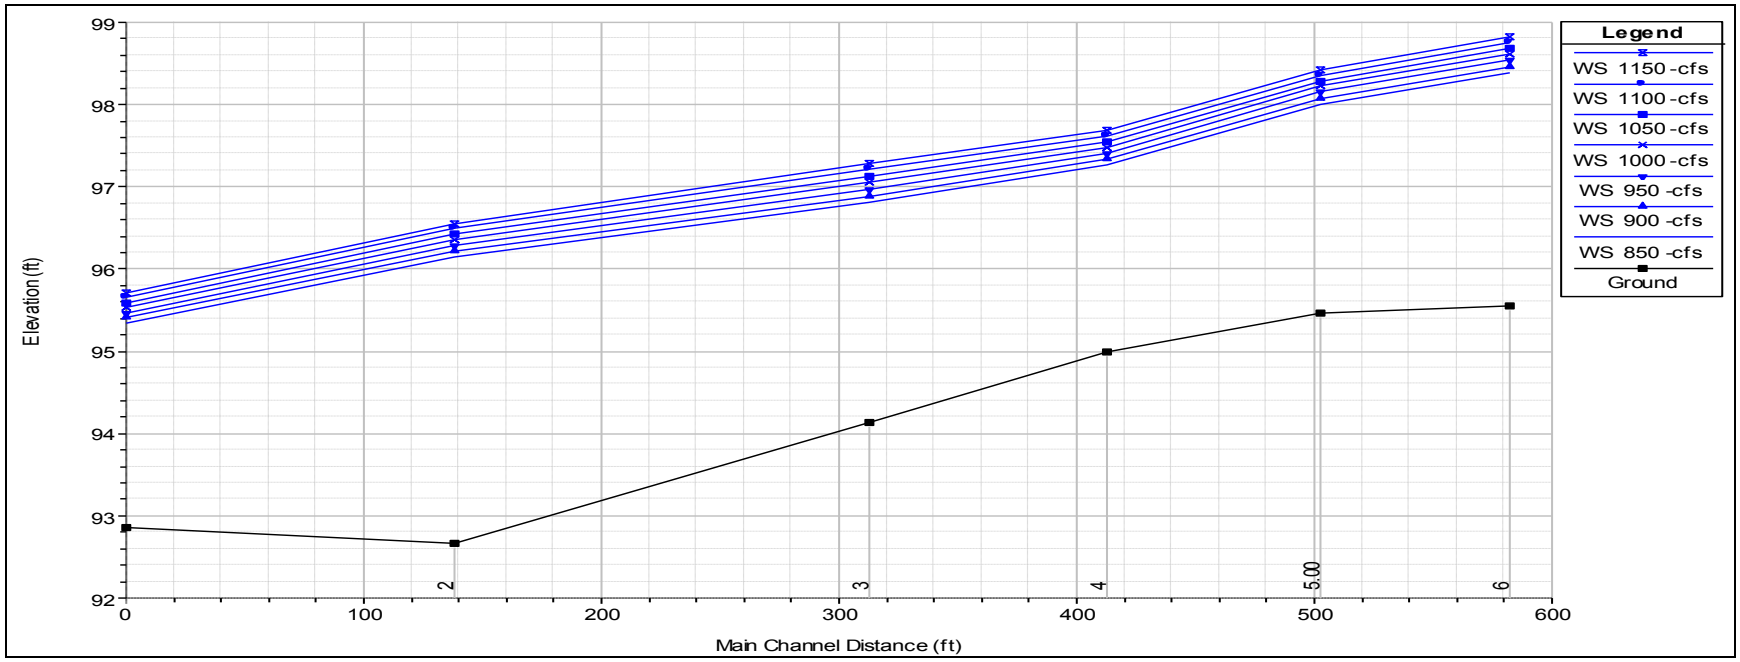

Figure 42 HEC-RAS longitudinal profile output for Reach FGUT1.6. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT1.6

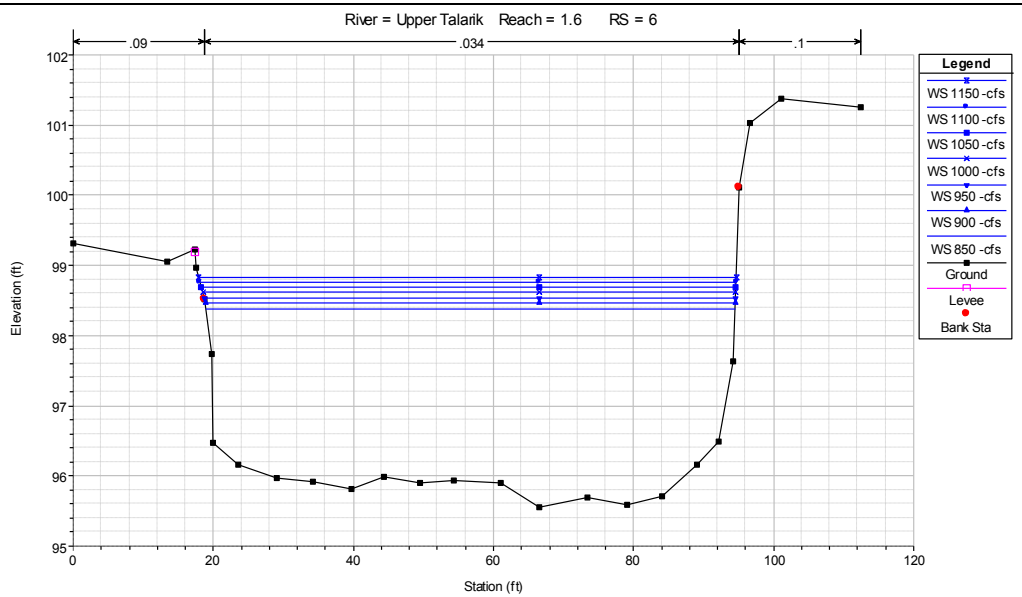

Figure 43 River Station (RS) 6 on River Reach FGUT1.6. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

	% Willow	**85**	
	% Grass	**5**	
	% Tree	**10**	

Site Overview. By incorporating the USGS stream gage UT100B into the hydraulic model, FGUT2 serves as a point of reference for the Upper Talarik Creek. Roughly two years of hydrology data (9/04 – 6/06) allowed for an idea of the frequency and magnitude of discharge events (see attached hydrograph).

During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed 11 cross-sections along 700 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 6 and 5 characterize the riffle which serves as the reference reach. Sections 6 through 1 characterize the downstream pool. Section 9 captures UT100B and Sections 6 through 9 characterize the pool downstream of the gage.

According to the hydrograph, channel-forming discharges most likely do not exceed 800-900 cfs because of the frequency and duration of events. For Section 6, shear increases with decreasing discharge. This phenomenon may be attributed to a steep slope and narrow channel which causes supercritical conditions during lower discharges and therefore artificially high shear. For a Shields number of 0.017, the D_{84} begins movement between 800 and 900 cfs through the upper sections (Sections 11-7) and by 900 cfs on Section 4. For a Shields number of 0.026, the D_{50} begins to move between 700 and 800 cfs through many of the sections. The height of the deposition on the gravel bar provides a good indication of channel forming discharges. A flow of 700 cfs comes close to matching the top of the upper gravel bar (Sections 11-6) while 1100 cfs overtops the bar by 0.5-1'.

The reference reach sections (Sections 5 and 6) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGUT2

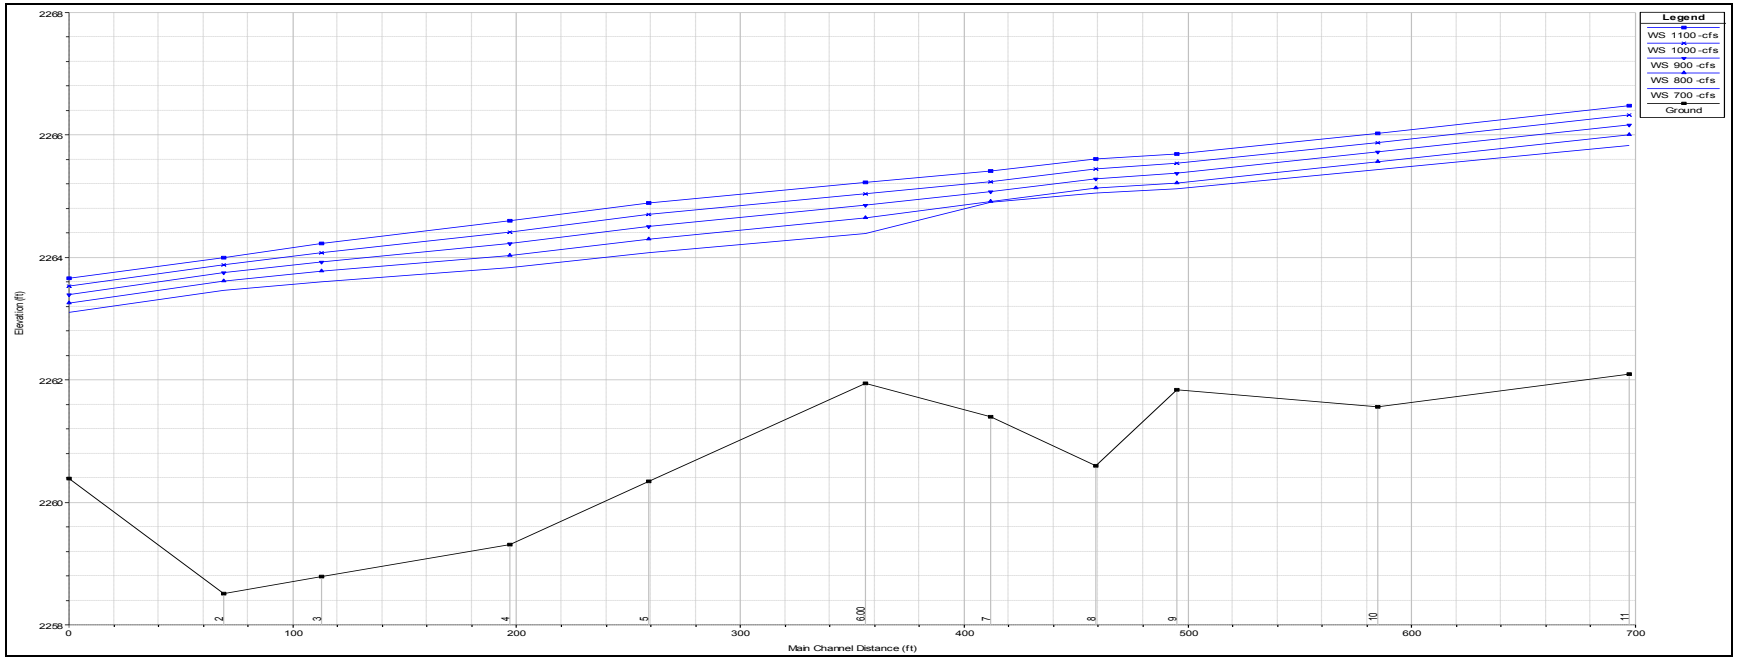

Figure 49 HEC-RAS longitudinal profile output for ReachFGUT2. Numbers 1-11 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT2

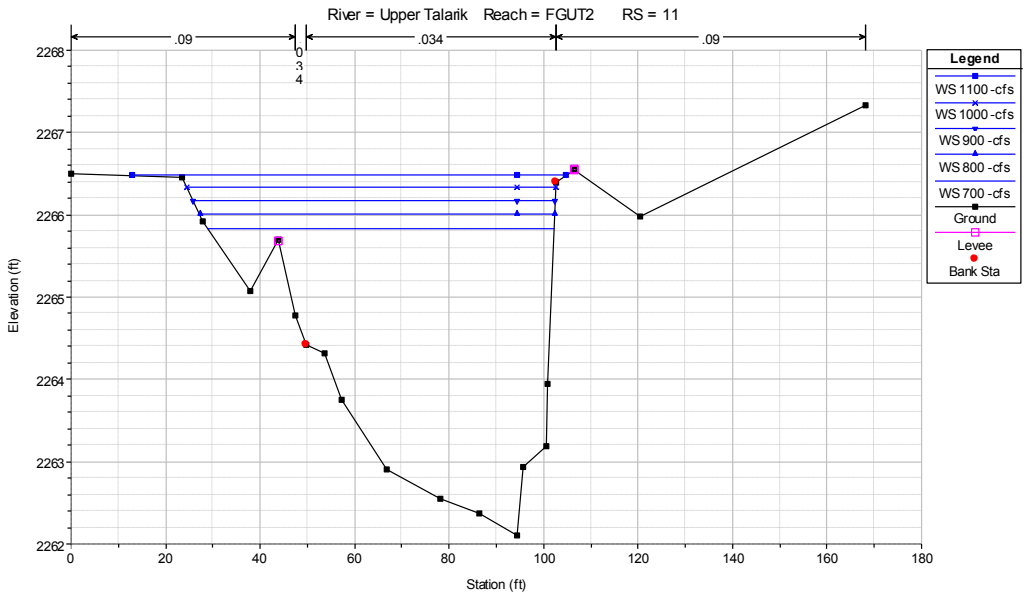

Figure 50 River Station (RS) 11 on River Reach FGUT2. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

SITE DESCRIPTION: FGUT3

Site Characteristics.

Site Name	**FGUT3**		
Discharge (cfs)	**775 (675-875)**	Width (ft)	**72.2 (69.0-77.6)**
Slope	**0.0021**	Cross-sectional Area (ft^2)	**183 (161-207)**
D_{50}	**46**	D_{84}	**85**
Lat/Long Location	**N59.80240 W155.21755**	Drainage Area (mi^2)	**80**
% Willow	**95**		
% Grass	**5**		
% Tree	**0**		

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 415 feet of channel length. Section 1 serves as the downstream hydraulic control for the model. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 7 through 4 characterize the riffle which serves as the reference reach. A pebble count was taken between Sections 6 and 7. Overwidened due to the entrance of a backwater/side channel along the left bank, Sections 7 and 8 required the addition of an ineffective flow boundary to account for the lack of conveyance during high flows. Lacking a pool downstream of the reference riffle, Sections 4 through 1 capture a series of grade breaks associated with riffles and glides.

Mobility of the D_{84} and D_{50} through the reference reach is limited to Section 7 where for a Shields of 0.017, the D_{84} moves at 850 cfs and for a Shields number of 0.026, the D_{50} moves before 675 cfs. The INCIPIENT MOTION ANALYSIS: provides some evidence for a range of channel forming discharges. The cross-section geometry and channel forming indicators through the reach further support this range. A right bank inflection point and the edge of the willows along Sections 7 and 8 matches a discharge of 725 cfs. A left bank inflection point and the edge of the willows along Sections 5 and 4 match a flow of 875 cfs. Discharges between 675 and 875 cfs overtop the gravel bar up to 0.5' along Sections 1 and 2.

The reference reach sections (Sections 7 through 4), with the exception of Section 7, provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGUT3

HEC-RAS LONGITUDINAL PROFILE: FGUT3

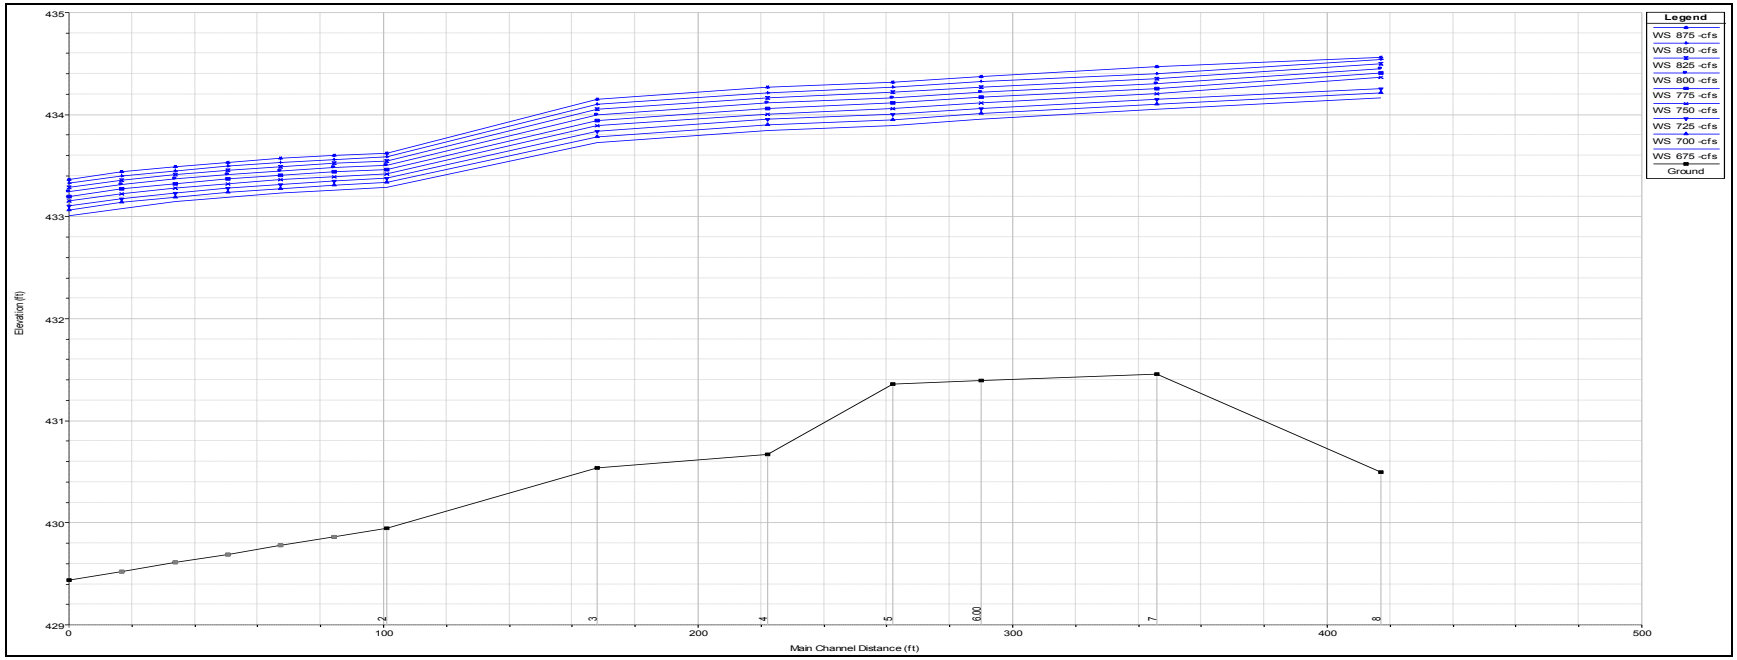

Figure 62 HEC-RAS longitudinal profile output for Reach FGUT3. Numbers 1-8 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT3

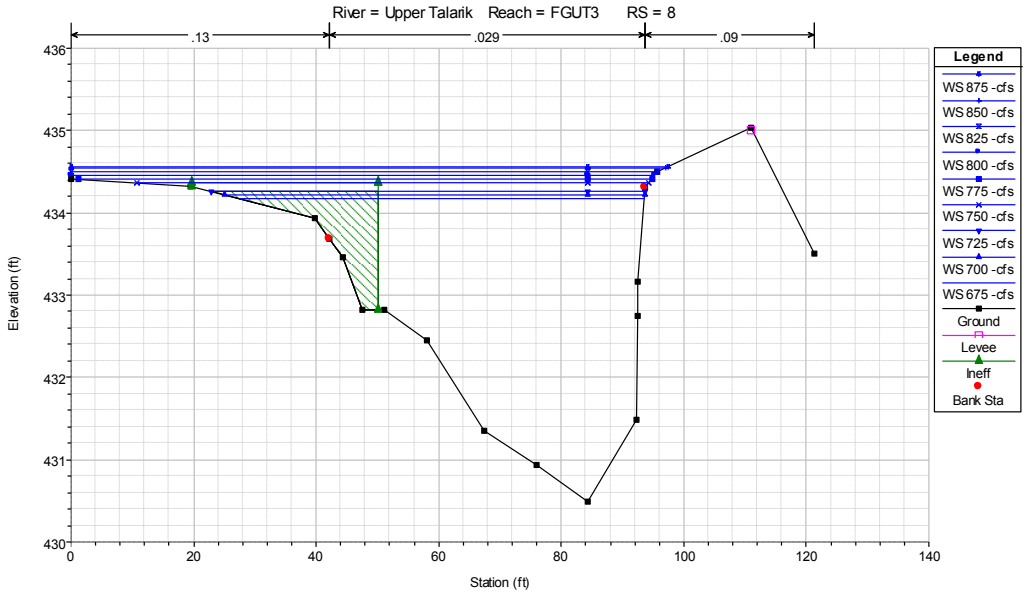

Figure 63 River Station (RS) 8 on River Reach FGUT3. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 415 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. This cross-section was co-located with ISF site 05-UTC2-RF1. Sections 6 through 4 characterize the riffle which serves as the reference reach. Cross-section 5 was resurveyed in September 2007. The pebble count was taken through Section 5. Coarse bed material through the riffle was thought to be immobile. Pebble count 1 was modified to account for this and both the original distribution as well as the modified one are included in the analysis.

For a Shields number of 0.017, the D_{84} of the modified distribution moves through Section 5 between 750 and 800 cfs but does not move through Sections 6 or 4 within the range of channel forming discharges. For a Shields number of 0.026, the D_{50} moves well before 600 cfs through the reference reach. Discharges between 700 and 750 cfs match the geometry at Sections 4, 3 and 2 well.

The reference reach sections (Sections 6 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGUT4

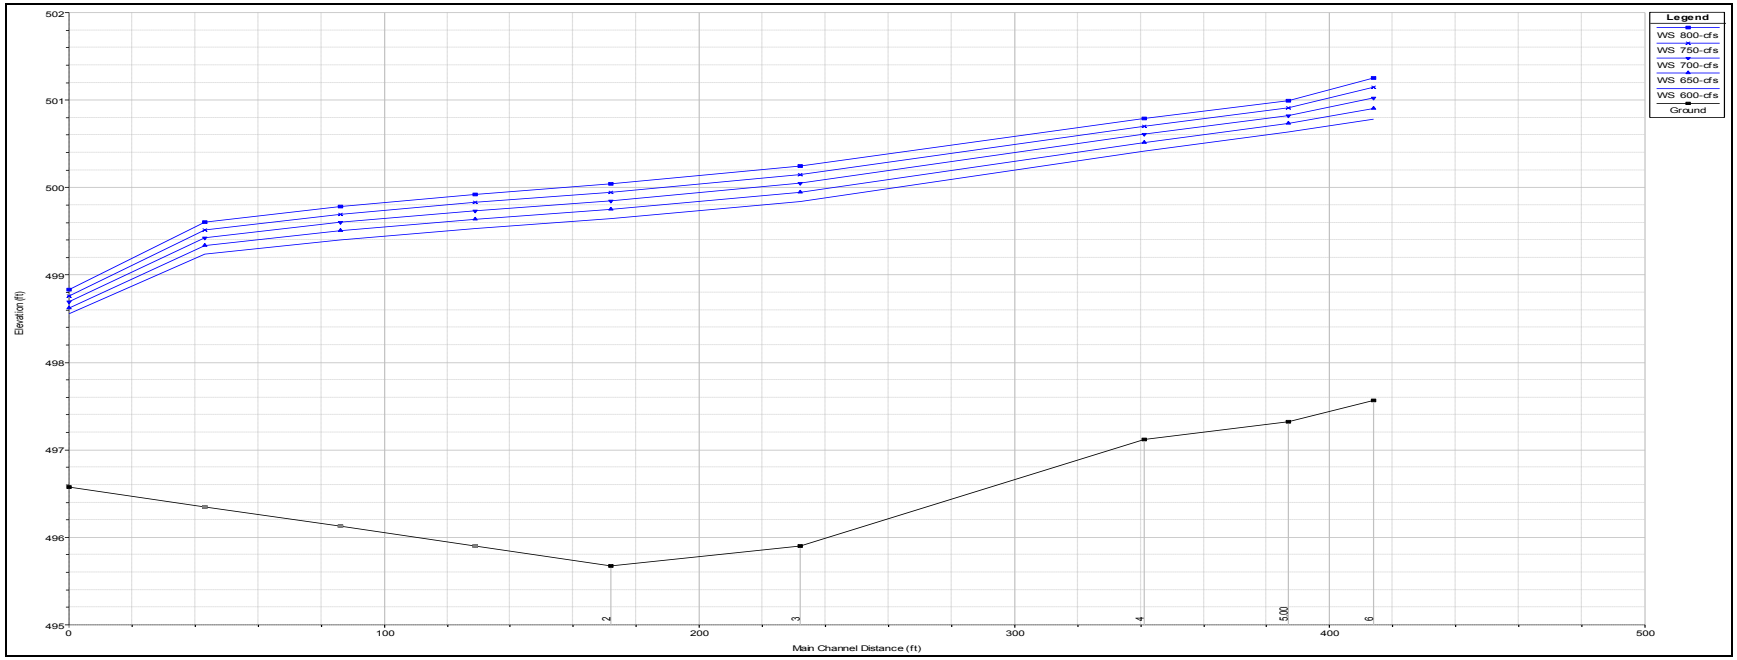

Figure 71 HEC-RAS longitudinal profile output for Reach FGUT4. Numbers 1-7 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT4

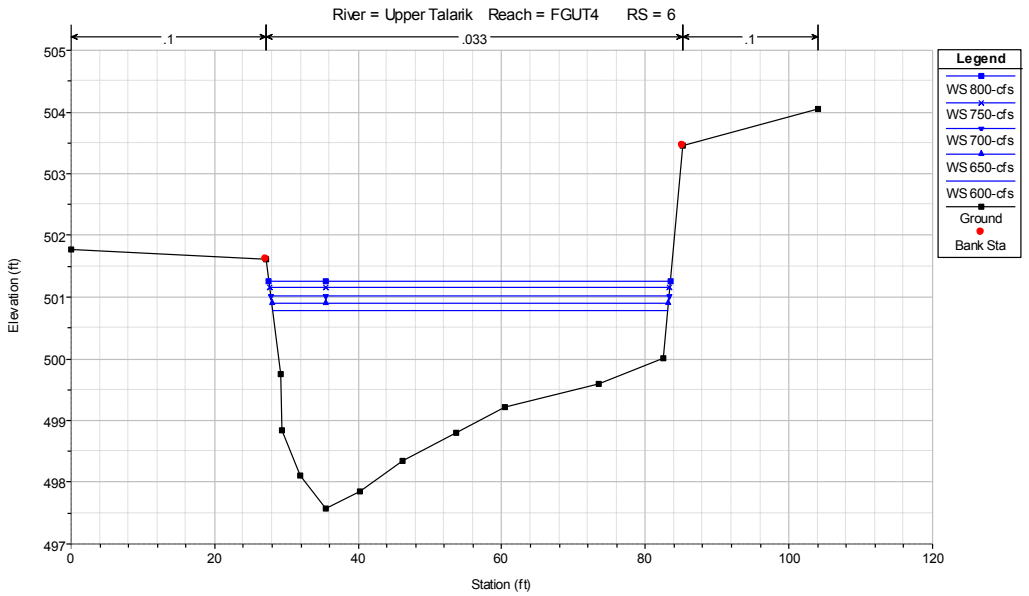

Figure 72 River Station (RS) 6 on River Reach FGUT4. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT4

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed five cross-sections along 200 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. This cross-section was co-located with ISF site 05-UTC2-RF1. Sections 5 through 3 characterize the riffle which serves as the reference reach. The pebble count was taken through Section 4. Coarse bed material through the riffle was thought to be immobile. Pebble count 1 was modified to account for this and both the original distribution as well as the modified one are included in the analysis.

For a Shields number of 0.017, the D_{84} of the modified pebble count distribution move through Section 4 by 600 cfs but does not move through Sections 5 or 3 within the range of channel forming discharges. For a Shields number of 0.026, the D_{50} of both distributions moves by 550 cfs through the reference reach. Discharges between 500 and 650 cfs match an inflection point along the right bank through the reference reach.

The reference reach sections (Sections 5 through 3) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

% Willow	**70**		
% Grass	**30**		
% Tree	**0**		

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 370 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Lacking any well-formed riffle, the pebble count was conducted on the crest of a pool/glide (Section 5). Sections 7 through 5 characterize that pool/glide which serve as the reference reach. Sections 4 through 1 characterize the pool.

For a Shields number of 0.017, the D_{84} moves through Section 5 before 420 cfs, through Section 7 at 500 cfs, and through Section 6 at 570 cfs. For a Shields number of 0.026, the D_{50} moves by 420 cfs through all cross-sections. A discharge of 530 cfs matches the right bank through the upper glide/pool (Sections 7 and 6). The height of the deposition on the gravel bar provides a good indication of channel forming discharges. Discharges between 480 and 500 cfs overtop the gravel bar along the right bank of the downstream pool (Section 2) while a discharge of 570 matches the left bank inflection point of the same section.

Without a well-defined riffle, channel width and cross-sectional area were averaged through the upstream pool/glide (Sections 7 through 5) for the range of flows.

SITE DESCRIPTION: FGUT7

Site Characteristics.

Site Name		FGUT7	
Discharge (cfs)	**500 (400-600)**	Width (ft)	**61.0 (55.0-64.9)**
Slope	**0.0024**	Cross-sectional Area (ft^2)	**138 (112-159)**
D_{50}	**34**	D_{84}	**63**
Lat/Long Location	**N59.88017 W155.16960**	Drainage Area (mi^2)	**48**
% Willow	**80**		
% Grass	**20**		
% Tree	**0**		

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 360 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool/run. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 6 and 5 characterize a riffle while Section 7 was taken through a run/glide. Both the riffle and run/glide serve as the reference reach for this site. Sections 4 through 1 characterize a pool. A vegetated island close to the right bank is captured in Sections 2 and 3. The HDR hydrology gage (UT100C2) is located just upstream of Section 3, as the channel widens. Section 4 is co-located with ISF site 07-UTC2-RN4.

For a Shields number of 0.017, the D_{84} moves through Sections 5 and 4 before 400 cfs, but do not move through Sections 7 and 6 by 600 cfs. For a Shields number of 0.026, the D_{50} moves through Sections 5 and 4 by 400 cfs and by 550 cfs through Sections 7 and 6. Flows between 500 and 600 cfs match a right bank inflection point and willow line through the reference reach and Section 7. Flows between 400 and 500 cfs overtop the left bank through the same sections. The top of the island is matched by flows between 400 and 550 cfs. While the incipient motion analysis through Sections 5 and 4 shows low flows mobilizing the substrate, higher flows were chosen for the channel forming discharge based on the incipient motion through Sections 6 and 7 and the geometry which was in strong agreement through the reach.

The reference reach sections (Sections 7 through 5) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGUT7

HEC-RAS LONGITUDINAL PROFILE: FGUT7

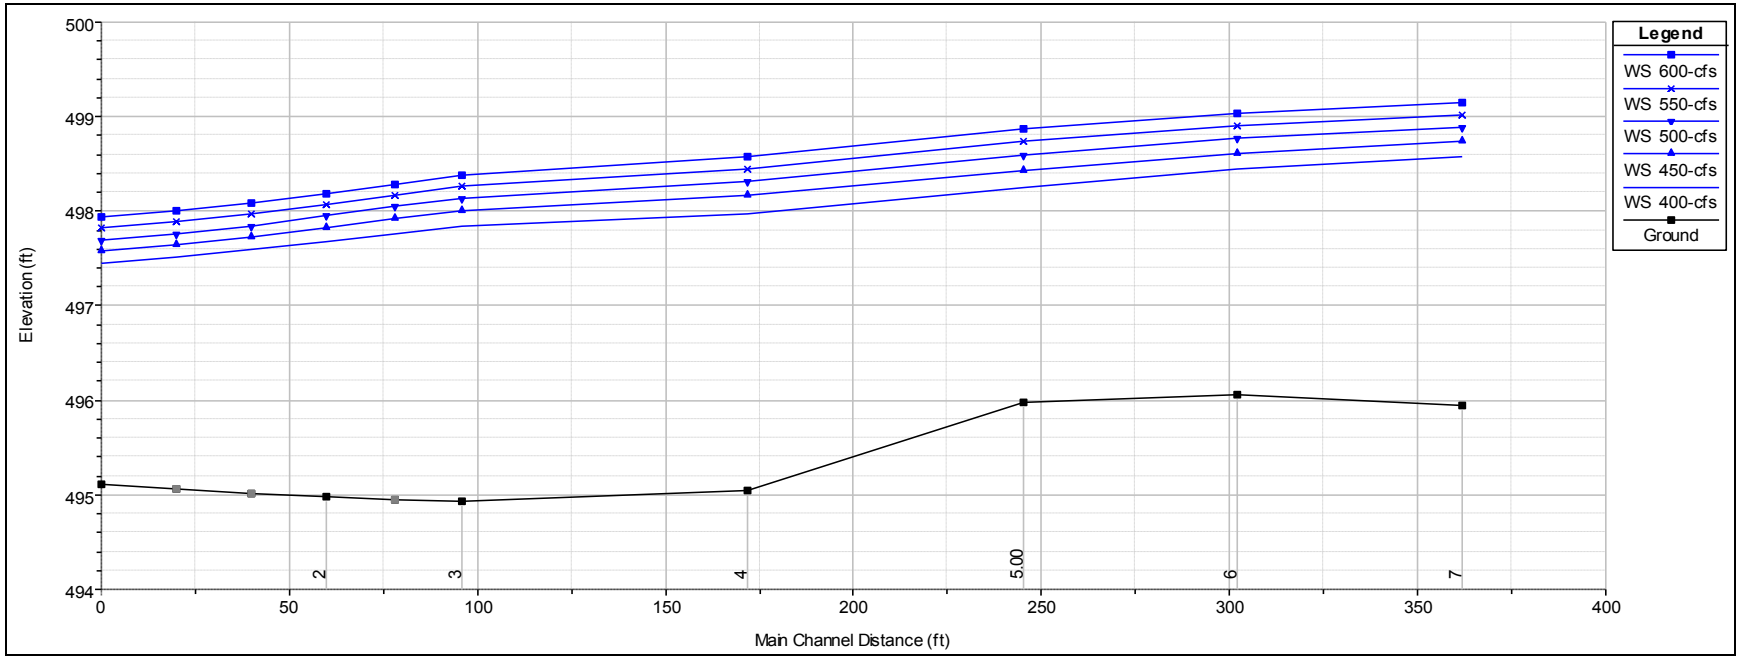

Figure 92 HEC-RAS longitudinal profile output for Reach FGUT7. Numbers 1-7 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT7

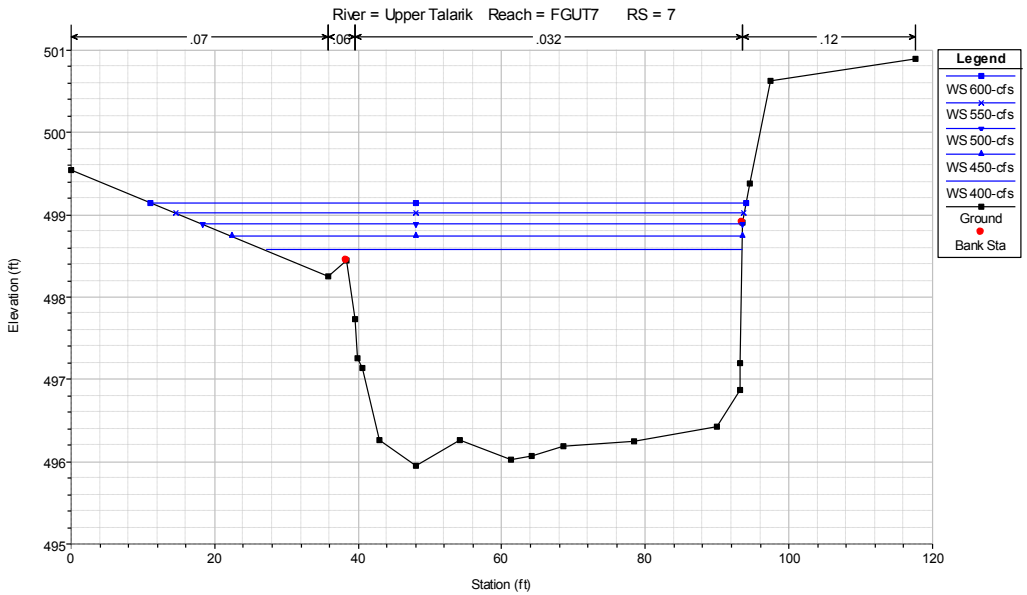

Figure 93 River Station (RS) 7 on River Reach FGUT7. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 185 feet of channel length. Sections 5 through 7 represent a short riffle beginning with a pool tailout at the upstream boundary (Section 7). These sections serve as the reference reach. Sections 2 through 4 represent the downstream pool and Section 1 represents the downstream hydraulic control for the area surveyed. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Pebble counts were taken along Sections 6 and 7. The first pebble count was taken at the pool tailout near Section 7. The second pebble count was taken between Sections 5 and 6 through the short riffle.

For a Shields number of 0.017, the D_{84} of both pebble count's 1 and 2 move through Sections 6 and 5 between 350 and 425 cfs but is immobile through Section 7. For a Shields number of 0.026, the D_{50} for both pebble counts moves through Sections 6 and 5 between 200 and 325 cfs. Flows between 200 and 275 cfs match inflection points on all cross-sections. Higher flows, which include those flows ranging from 300 to 400 cfs match inflection points on Sections 7, 6 and 1. A flow of 325 cfs was chosen as the channel forming discharge, as it splits the difference between the higher flows which the incipient motion analysis suggests and the lower flows supported by the channel geometries.

The reference reach sections (Sections 7 through 5), provides the best representation of the channel dimensions and was used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGUT8

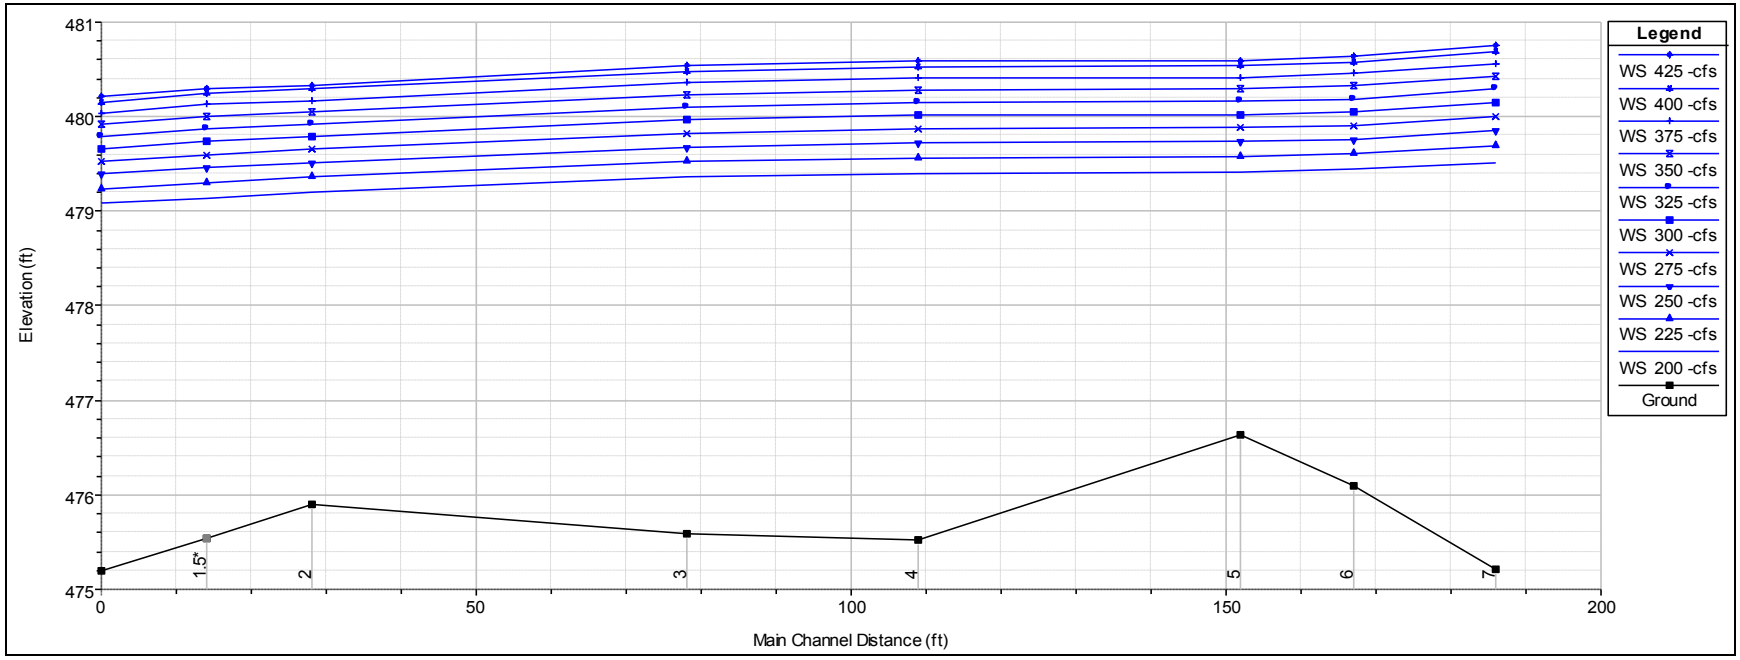

Figure 100 HEC-RAS longitudinal profile output for Reach FGUT8. Numbers 1-7 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT8

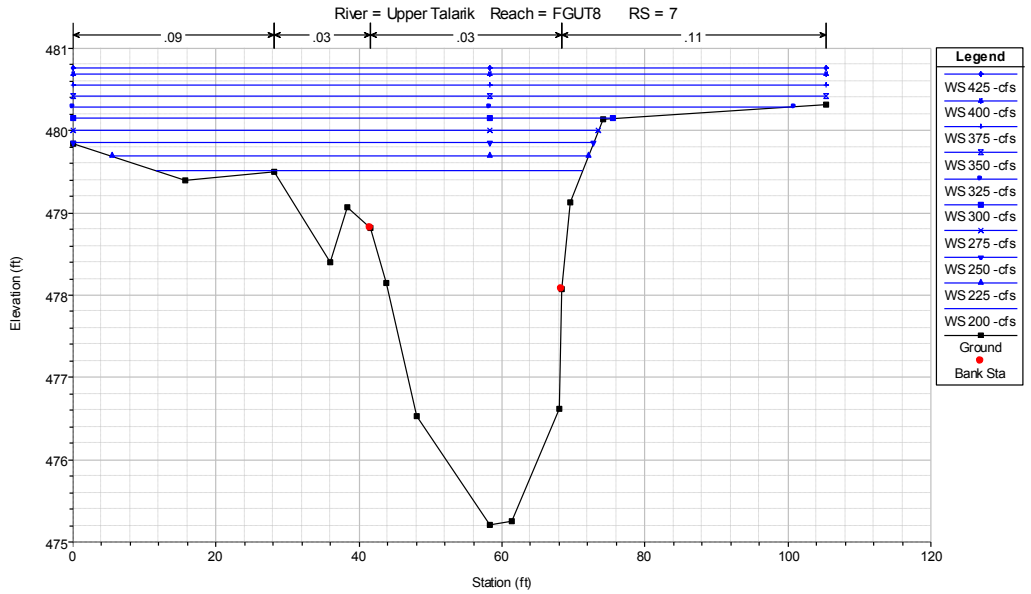

Figure 101 River Station (RS) 7 on River Reach FGUT8. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 220 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. The downstream control was taken through a transverse bar. A scour hole and a scalloped bank existed at the downstream face of the transverse bar. To account for this, Section 1 was modeled to follow the crest of the transverse bar, adjusting the width to match average channel width. Sections 3 through 5 characterize the riffle which serves as the reference reach. A relic channel exists behind a gravel bar along the right bank of the riffle. Sections 5 through 6 characterize a run/glide upstream of the riffle. Sections 3 through 1 characterize the downstream pool.

The incipient motion analysis and the geometry through the reach show strong agreement. For a Shields number of 0.017, the D_{84} begins to move through Sections 3 and 5 at a flow of 350 cfs, at a flow of 250 cfs through Section 6 and 300 cfs through Section 4. For a Shields number of 0.026, the D_{50} begins to move through the riffle within the range of channel forming discharges. Flows between 275 and 325 cfs matches the geometry well, overtopping the mid-channel bar on Section 1, the right bank on Section 2, and the left bank on Sections 3, 5 and 6.

The reference reach sections (Sections 5 through 3) along with the upstream glide (Section 6) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed six cross-sections along 230 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the downstream pool. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 4 and 3 characterize the riffle through which the pebble count was taken. This riffle also serves as the reference reach. Sections 6 through 4 and Sections 3 through 1 characterize the two pools surveyed within this reach. The HDR hydrology gage (UT100D) is located between Sections 1 and 2. Roughly two years of hydrology data (7/04 – 6/06) allowed for an idea of the frequency and magnitude of discharge events (see attached hydrograph).

According to the two years of hydrology data documented in the UT100D hydrograph, flows between 130 and 150 cfs appear to approximate the frequency of a channel-forming discharge. The incipient motion analysis shows that both the D_{50} and D_{84} move through the reach well before 120 cfs. Therefore, the choice of channel forming discharges relies on the hydrology and geometry through this reach. Flows between 150 and 180 cfs match the inflection point along the left bank throughout the reach. On cross-section 3, flows between 130 and 150 cfs overtop both banks.

The reference reach sections (Sections 4 and 3) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGUT9

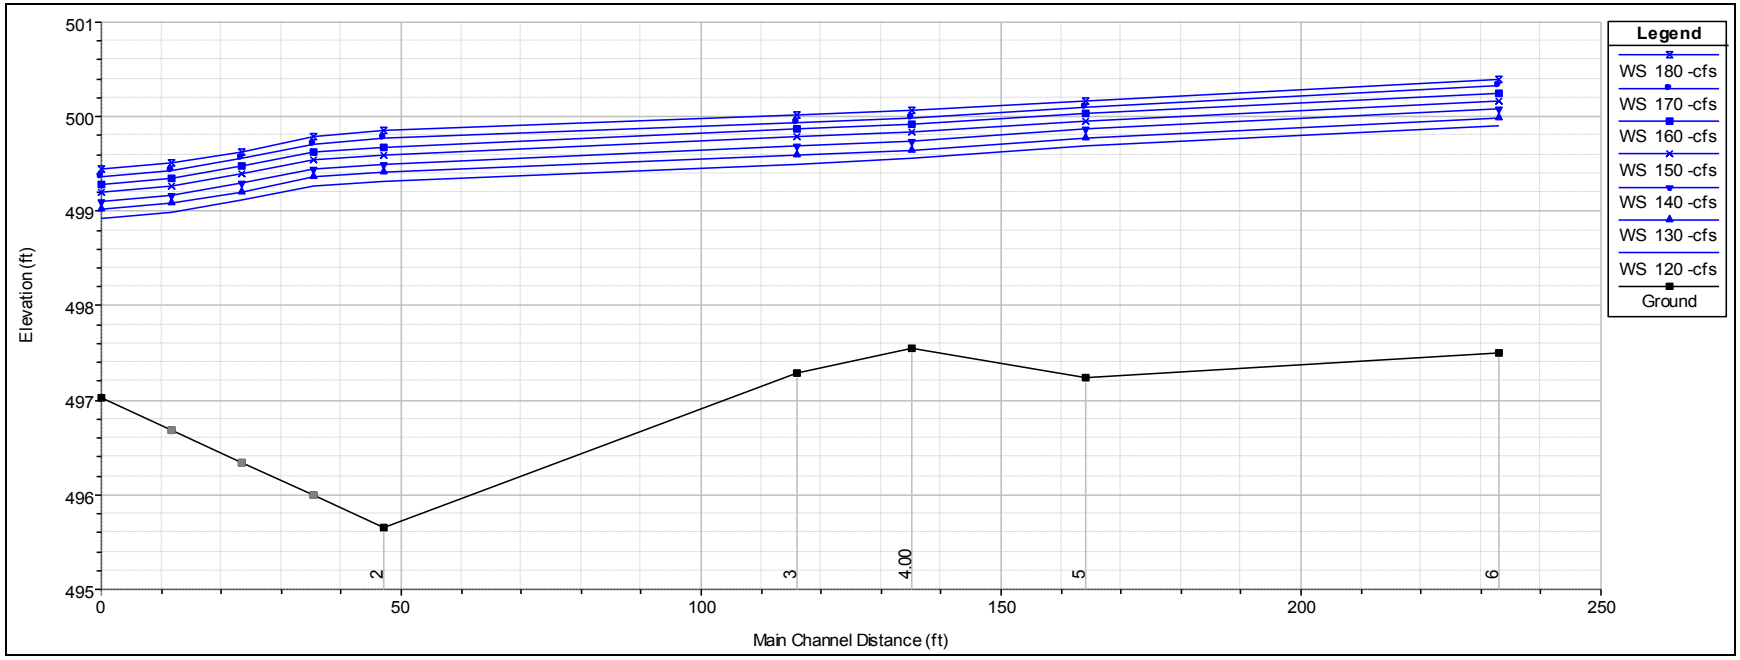

Figure 115 HEC-RAS longitudinal profile output for Reach FGUT9. Numbers 1-6 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT9

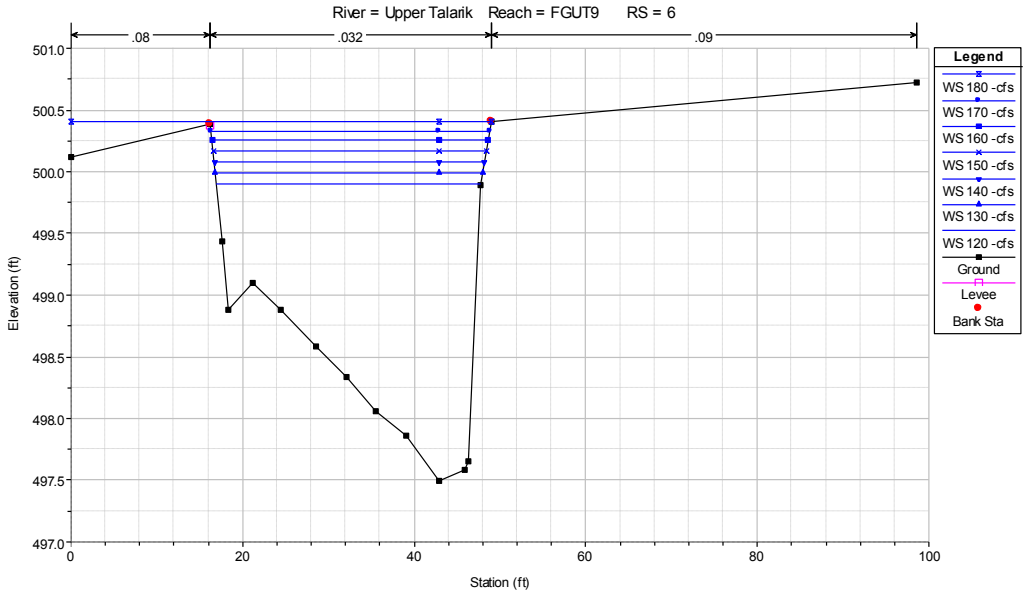

Figure 116 River Station (RS) 6 on River Reach FGUT9. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGUT9

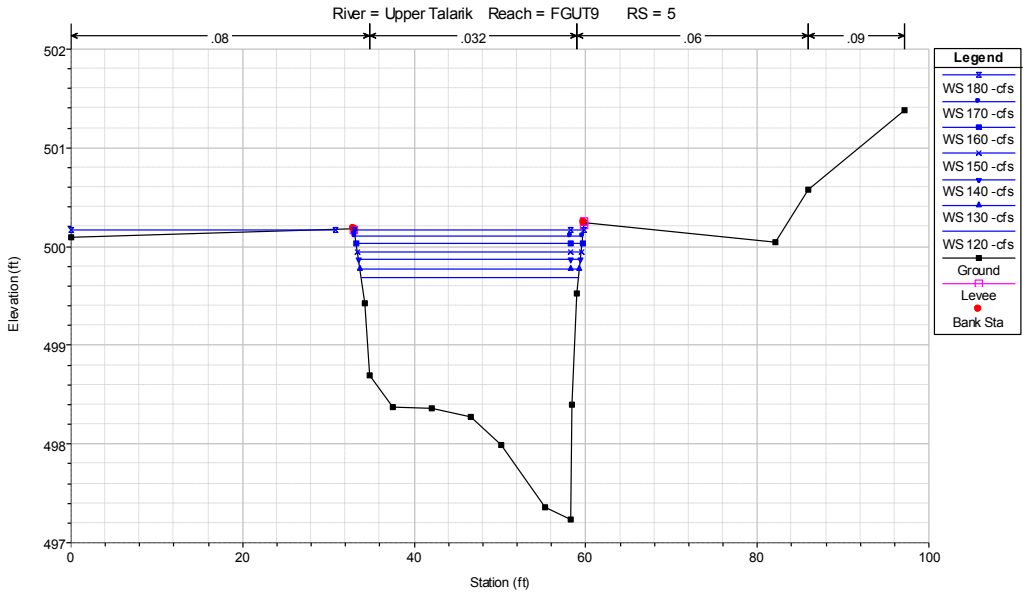

Figure 117 River Station (RS) 5 on River Reach FGUT9. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

D_{50}	**40**	D_{84}	**82**
Lat/Long Location	**N59.90897 W155.25470**	Drainage Area (mi^2)	**6**
% Willow		**40**	
% Grass		**60**	
% Tree		**0**	

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed seven cross-sections along 110 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the downstream pool. For this site, the DEM-derived reach-average slope is a more suitable boundary condition than the surveyed water surface slope, as the surveyed water surface slope appears to artificially backwater the model. Sections 3 through 7 characterize the riffle which serves as the reference reach. Sections 1 through 3 characterize the downstream pool. The pebble count was taken between Sections 5 and 6.

For a Shields number of 0.017, the D_{84} begins to move through Sections 7 and 6 before 75 cfs but does not move through the rest of the sections in the reference reach within the range of channel forming flows. For Sections 7 through 5, shear increases with decreasing flow. This phenomenon may be attributed to a steep slope and narrow channel which causes supercritical conditions during lower flows and therefore artificially high shear. A flow of 125 cfs matches the geometry through the reach well, hitting the inflection point along the left bank for most sections. At the lower end of the range of channel forming discharges, 75 cfs matches a lower inflection point and vegetation line along the left bank.

The reference reach sections (Sections 7 through 3) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

	% Willow	**30**	
	% Grass	**70**	
	% Tree	**0**	

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed eight cross-sections along 100 feet of channel length. Section 1 serves as the downstream hydraulic control for the model, while Section 2 represents the hydraulic control for the pool. Sections 4 through 6 characterize the riffle, which serves as the reference reach, and through which the pebble count was taken (along Section 5). The HDR hydrology gage (UT100E) is located between Sections 2 and 3. Roughly two years of hydrology data (7/04 – 6/06) allowed for an idea of the frequency and magnitude of discharge events (see attached hydrograph). A preliminary rating curve formulated by Knight-Piesold and based on the instantaneous discharge measurements collected by HDR was provided to IFI by HDR on 2/11/2008. Incorporation of the cross-section taken by HDR through the gage into the FGUT11 hydraulic model allowed for the calibration of Manning's channel roughness based on the stage discharge relationship defined by the rating curve (See Attachment 1 for details). Based on the results of this exercise, channel roughness for the flows of interest are roughly equal 0.047. While this value was greater than any other values chosen for the remainder of the 51 FG sites, the high gradient and coarse bed material support its use.

Flows between 35 and 55 cfs match the geometry through the entire reach well. These flows are in agreement with the limited hydrology data. For a Shields number of 0.017, the D_{84} begins movement through the upper sections of the reference reach (6 and 5) before 35 cfs but does not move through Section 4 by 55 cfs. Similar to the D_{84}, the D_{50} is extremely mobile through all of the reference reach sections.

The reference reach sections (Sections 6 through 4) provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS OUTPUT SUMMARY TABLE: FGUT11

SITE DESCRIPTION: FGMK1

Site Name	**FGMK1**		
Discharge (cfs)	**2400 (2000-2800)**	Width (ft)	**149.5 (124.2-170.5)**
Slope	**0.0009**	Cross-sectional Area (ft^2)	**595 (502-697)**
(1) D_{50}	**31**	D_{84}	**60**
(2) D_{50}	**51**	D_{84}	**80**
(3) D_{50}	**41**	D_{84}	**82**
Lat/Long Location	**N59.85521 W155.82410**	Drainage Area (mi^2)	**227**
% Willow	**45**		
% Grass	**5**		
% Tree	**50**		

Site Overview. During Inter-fluve, Inc.'s field efforts in July 2007, field personnel surveyed nine cross-sections along 1330 feet of channel length. Section 1 serves as the downstream hydraulic control for the model and represents the crest of the pool. Sections 7 and 6 characterize a riffle. A side channel comes in just upstream of Section 6. During low flow conditions a mid-channel bar between Sections 6 and 7 causes transverse flow. Once flows increase, the bar likely gets washed away straightening out flow through the riffle. Sections 6 through 1 characterize the pool. Upstream of Section 7, two sections were surveyed through a glide. Sections 9 through 7 serve as the reference reach due to the overwidening of Section 6. Three pebble counts were conducted at this site; the first through and just upstream of Section 7 along the riffle crest, the second along the exposed gravel bar on the left bank, and the third just upstream of the bulk sample around the mid-channel bar between Sections 6 and 7.

Using those Shield's numbers determined experimentally on the North Fork Koktuli (0.016 and 0.024), besides the D_{50} from pebble count 1 (31 mm) moving through Section 9, the remainder of the D_{50} and D_{84}'s (for all of the three pebble counts) do not move through the riffle or upstream glide. Without empirical incipient motion data to calibrate these numbers with, and the observation that the sediment on the bed is in fact mobile, the incipient motion analysis is inconclusive. The left bank and top of the gravel bar on the left bank for all sections match flows between 2000 and 2200. Higher flows (2400-2800) correlate well with the right bank along Section 8 through 4, and Section 2.

Due to the overwidening of Section 6 because of the entrance of a side-channel, the deposition of material and the resultant transverse flow, Sections 9 through 7 provide the best representation of the channel dimensions and were used to find average channel width and cross-sectional area over the range of flows.

HEC-RAS LONGITUDINAL PROFILE: FGMK1

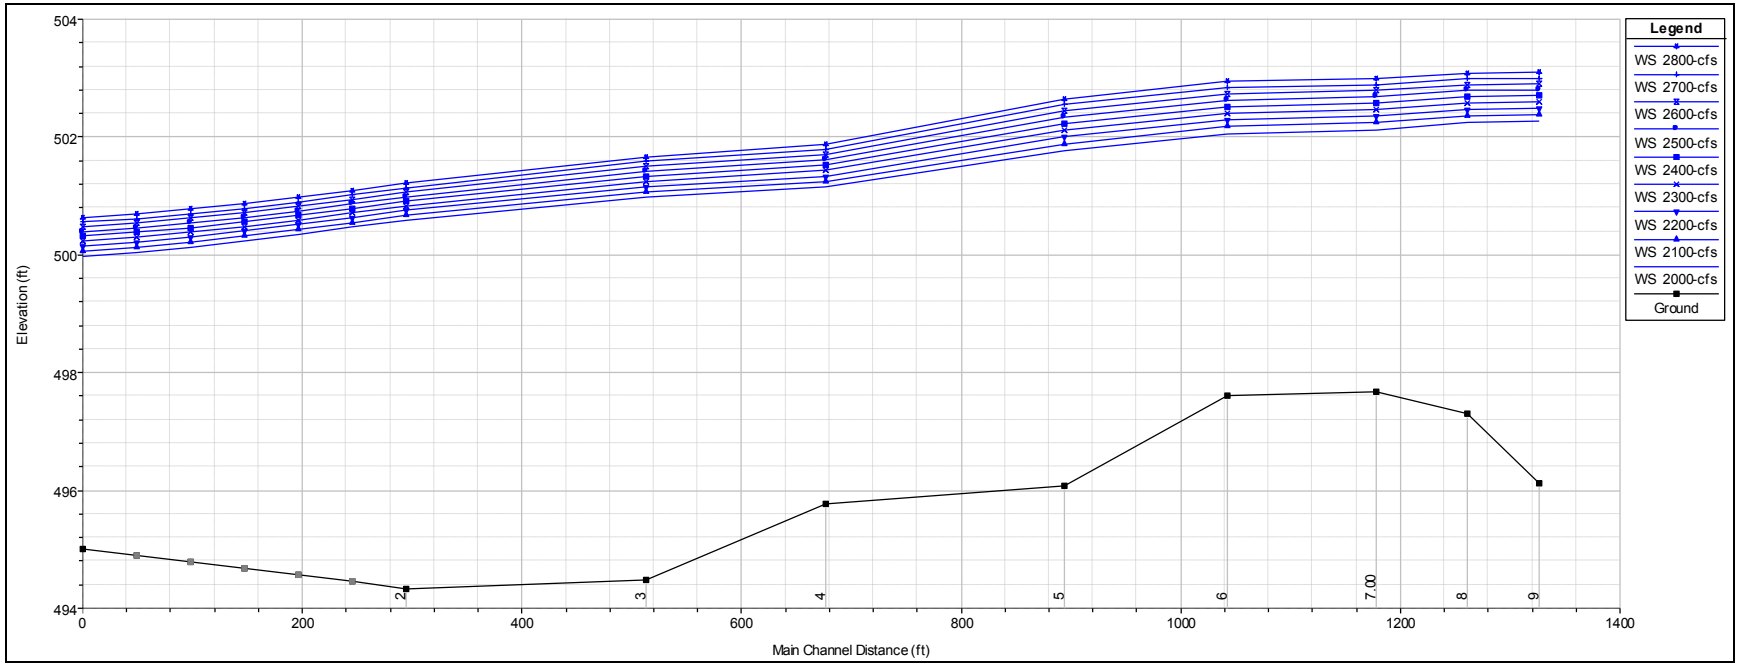

Figure 141 HEC-RAS longitudinal profile output for Reach FGMK1. Numbers 1-9 along the horizontal axis correlate to hydraulic cross-sections within the model. Main channel distance (ft) is distance upstream from cross-section 1 (at Main Channel Distance (ft) 0). Blue profile lines represent water surface elevations at selected discharges.

HEC-RAS CROSS-SECTIONS: FGMK1

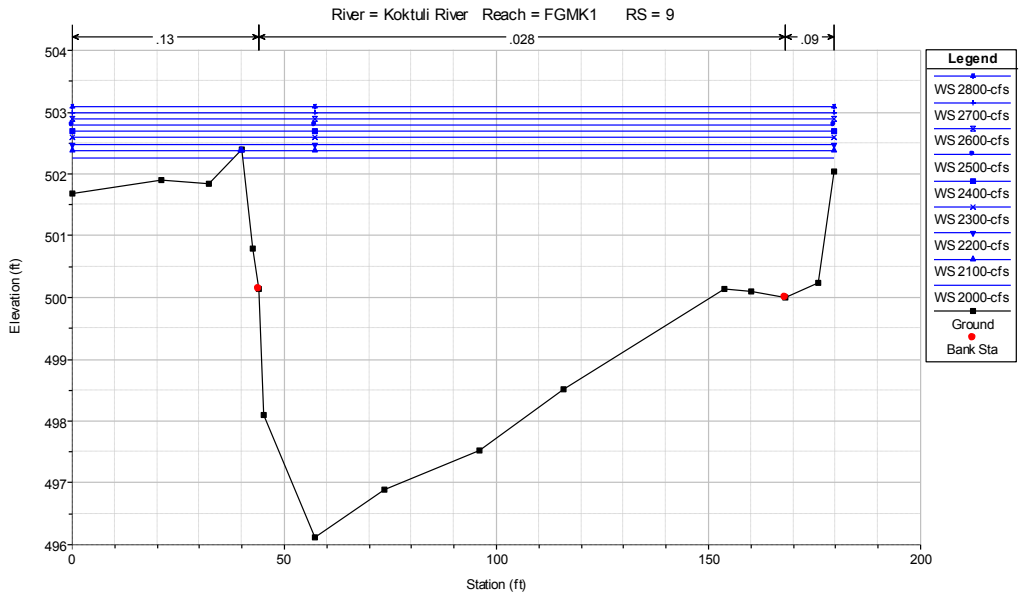

Figure 142 River Station (RS) 9 on River Reach FGMK1. Black line represents the channel ground facing downstream. Station (ft) is distance from the start of the cross-section (station 0). Blue lines represent water surface elevations at selected discharges.

ACRONYMS AND ABBREVIATIONS

EBD	environmental baseline document for Pebble Project
DLG	digital line graph
GIS	geographic information system
NFK	North Fork Koktuli River
SFK	South Fork Koktuli River
USGS	U.S. Geological Survey
UT	Upper Talarik Creek

DESCRIPTION OF WATERBODY NAMING CONVENTION

A hydrography dataset of the study area was created from 1:63,360 USGS DLG features as well as hand-digitized streams to be used as a base layer for maps and to create a continuous line network to facilitate linear referencing of features. Because the majority of the streams within the study area did not have official names or have multiple local names, stream codes were designated to allow for organization of data across all years of collection and all disciplines, as well as linear referencing. The stream code naming convention applied is an alpha-numeric system separated by periods which indicate a streams relative position within the stream network based on the hydrography of the stream from its outlet upstream to its headwaters.

In the study area, three streams were considered to be mainstem channels: North Fork Koktuli (NFK), South Fork Koktuli (SFK) and Upper Talarik Creek (UT). The first segment of the stream code consists of alphabetic characters and the number one, representing the mainstem channel. The numbers following the first period represent tributaries to the mainstem moving in an upstream direction; the number zero is used to represent the mainstem of the stream. For example, in Figure 1, UT1.0 represents Upper Talarik Creek mainstem, while UT1.410 identifies a tributary to Upper Talarik Creek. Given the length of the mainstems, a three-digit code was used to represent the tributaries of the mainstems because they were initially numbered based on maps, which may only include larger tributaries. The third digit in the naming convention allows for streams that are found during field reconnaissance to be numbered in a sequential upstream direction without changing the numbers of existing streams. For instance, a tributary to South Fork Koktuli downstream of SFK1.240 and upstream of SFK1.230, was designated a stream code of SFK1.235. The two-digit numbers following the second period identify tributaries of tributaries to the mainstem, numbered sequentially in an upstream direction. Accordingly, all subsequent two-digit numbers separated by periods represent tributaries to the stream indicated to the left of the respective period. For example, UT1.410.10 identifies a tributary to UT1.410, while UT1.410.10.10 represents a tributary to UT1.410.10 (Figure 1).

Ephemeral streams can be common in the headwater areas of the study area, varying with annual changes in precipitation. The stream naming convention requires that a placeholder be left for the stream to accommodate historical and potential future data collection. In Figure 1, note that a placeholder has been left for UT1.410.20, an ephemeral stream historically noted as being present between UT1.410.10 and UT1.410.30.

Stream codes for ponds and lakes located within stream channels were also designated in a similar manner. The codes were based on the stream code of the catchment, followed by a “P” and a number indicating the sequential order of the pond/lake in an upstream direction. For example, NFK 1.240.P1 indicates the first in-stream pond located on NFK 1.240 (Figure 2). By using the stream codes, use of local names, for which a single waterbody could have several, is avoided. For instance, NFK1.240.P1 is also known as Big Wiggly Lake as well as Butterfly Lake (Table 1).

15.2 Macroinvertebrates and Periphyton—Mine Study Area

15.2.1 Introduction

The macroinvertebrate and periphyton studies in the vicinity of the Pebble Deposit are part of the overall program of baseline investigations to describe the current aquatic conditions in the mine study area. Baseline information on macroinvertebrate and periphyton community assemblages is valued because they are essential components of the aquatic food web and their community structure, particularly with respect to the more sensitive taxa, is an indicator of habitat and water quality (Barbour et al., 1999; Merritt and Cummins, 1996). The streams in the area support commercial and sport fisheries that rely on the productivity of organisms lower on the food web, such as macroinvertebrates and periphyton.

Macroinvertebrates are organisms without a backbone and that are large enough to be seen without the aid of a microscope. Sampling of macroinvertebrates typically targets larval and pupal stages of organisms that live in or on the substrate of streams and lakes (De Pauw et al., 2006). Periphyton is micro-algae attached to rocks or other solid surfaces and was sampled in order to describe the primary producers within freshwater habitats in the mine study area. As with macroinvertebrates, periphytic organisms also are sensitive to changes in the aquatic environment and can be used as a monitoring tool for in situ primary productivity (ADF&G, 1998).

The following sections present the methodology for and findings of the macroinvertebrate and periphyton field studies conducted during the summers of 2004, 2005, and 2007. At the time of this writing, 3 years of data have been collected; however, for some data sets (e.g., Alaska Department of Fish and Game [ADF&G] periphyton methods, chlorophyll-*a*), only 2 years of baseline data exist because of a change in the sampling methods leading into the 2005 field season.

A range of macroinvertebrate and periphyton sample-collection methods was employed during the beginning stages of this project to determine which methods would work best in these systems. The variety of methods used contributes greatly to the robustness of the baseline data-collection program.

15.2.2 Study Objectives

The objective of the macroinvertebrate and periphyton field and laboratory program was to characterize diversity, abundance, and density of macroinvertebrates and periphyton within freshwater habitats in the mine study area.

15.2.3 Study Area

The mine study area for macroinvertebrate and periphyton studies includes stream and lake habitats. It is bounded on the west by the confluence of the north and south forks of the Koktuli River and on the east by the Upper Talarik Creek watershed (Figure 15.2-1). Study sites were located on the North Fork Koktuli River (NK), South Fork Koktuli River (SK), Kaskanak Creek (KC), Upper Talarik Creek (UT), Chulitna River (CR), Frying Pan Lake, and Big Wiggly Lake. The macroinvertebrate and periphyton study sites coincided with sampling sites for water quality, hydrology, and fish resources however, macroinvertebrate and periphyton studies were not required at all sites designated for the other studies.

Twenty sites were initially selected for sampling – 18 stream sites and one site each in Frying Pan Lake and Big Wiggly Lake. The number and location of the macroinvertebrate and periphyton study sites have evolved over time In addition, because the sampling program incorporated more sampling methods in 2005, and therefore more samples, the number of biological monitoring sites sampled for macroinvertebrates and periphyton was reduced to eight in 2005 (five in the immediate vicinity of the deposit). In 2007, 10 sites were sampled in the deposit area.

15.2.4 Scope of Work

Information review began in spring 2004 and field work was conducted during the 2004, 2005, and 2007 field seasons. Sample and data analysis was conducted throughout that time and continued into 2008. The macroinvertebrate and periphyton studies were conducted in accordance with the applicable procedures described in Chapter 11 of the consolidated study program for the environmental baseline studies (see Appendix E of this environmental baseline document). Overall quality assurance (QA) and quality control (QC) for the baseline studies can be found in the *Draft Environmental Baseline Studies, Proposed 2004 Quality Assurance Project Plan* (see Appendix G of this environmental baseline document). Andra Love, Isaac Watkins, Lynn Spencer, Josh Hedberg, Brian Cook, Jessica Manifold, and Erin Cunningham of HDR Alaska, Inc., and Sally Morsell of Northern Ecological Services conducted the studies.

The 2004 sampling program consisted of the following tasks:

- Macroinvertebrate sampling, ASCI method. One composite ASCI sample was collected at each site.
- Macroinvertebrate sampling, drift-net method. Five drift nets were employed at each site, and material was combined into one composite sample.
- Macroinvertebrate sampling (lakes) using a modified ASCI method. One composite sample was collected for each site.
- Periphyton sampling modified Rapid Bioassessment Protocol (RBP) method (diatom community). One composite RBP sample was collected at each site.
- Ambient water-quality measurements. One measurement of each parameter was recorded at each site.

Preliminary analysis of 2004 data and discussions on proposed data use and conditions in the study area resulted in a decision to modify the sampling program for 2005 and 2007 to consist of the following tasks:

- Macroinvertebrate sampling (streams) using the ASCI method. One composite sample was collected at each site.
- Macroinvertebrate sampling (streams) using the Surber sampler semi-quantitative method. Five samples were collected at each site.
- Macroinvertebrate sampling (lakes) using a modified ASCI method. One composite sample was collected at each site.

- Periphyton sampling using the ADF&G method. Ten chlorophyll-*a* samples were collected at each site.
- Ambient water-quality measurements. One measurement of each parameter was recorded at each site.

15.2.5 Macroinvertebrate Methods

Detailed descriptions of field protocols for the macroinvertebrate sampling can be found in *Draft Environmental Baseline Studies, 2005 Field Sampling Plan, Fish and Aquatic Habitat* (Appendix F of this environmental baseline document). The number of sampling sites in the study area was reduced from 20 in 2004 to 8 in 2005, and 10 sites were sampled in 2007 (Table 15.2-1). Sampling frequency was reduced from two sampling events in 2004 to one in 2005 and one in 2007. The reduction in sample sites and frequency in 2005 allowed for more intensely sampled stream reaches at selected sites; the addition of Surber sampling required a six-fold increase in the number of samples collected and processed at each site.

15.2.5.1 Field Sampling Protocol

In 2004, sampling occurred from June 1 through June 6 and from August 14 through August 18. In 2005, sampling occurred from June 10 through June 13, and in 2007 sampling was conducted June 13 through June 15. The field team documented the location of each 100-meter-long stream reach using a global positioning system (GPS) and flagged the locations to ensure that subsequent sampling would occur in the same areas. At each site, macroinvertebrate sampling and periphyton sampling were conducted concurrently. Generally, three team members began the collection process at the downstream end of the stream reach and worked upstream for 100 meters. Two team members collected macroinvertebrate samples, and the third member collected periphyton samples. The concurrent sampling of macroinvertebrates and periphyton was intended to avoid site disturbance upstream of sample collection.

For QA and QC, duplicate samples were collected at a minimum of 10 percent of the sample sites on streams during the 2004, 2005, and 2007 sampling events. After sampling, the following items were verified:

- Labeling on all sample bottles was complete and readable.
- All sample bottles were accounted for.
- All samples had sufficient preservative.

ASCI Sampling in 2004, 2005, and 2007

In accordance with ASCI protocols (Major and Barbour, 2001), 20 subsamples were collected in the 100-meter reach at each sampling site and then were combined into a single composite sample for each site. The subsamples were collected from the habitat types within the reach based on proportionate habitat representation; for example, if 50 percent of the stream bottom was estimated to be cobble/riffle habitat, 10 of the 20 subsamples (50 percent) were collected from cobble/riffle habitat. Common in-stream habitats include undercut banks, snags, cobbles/riffles, emergent vegetation, and sand or soft sediment. The calculations of habitat representation were recorded on data sheets similar to those found in the

ASCI protocols. Other parameters noted on the habitat-assessment data sheets include air and water temperature, riparian vegetation, signs of erosion, latitude and longitude, and canopy cover. Pictures were taken at each site to document local conditions.

Samples were collected using a D-frame kick net with 363-micrometer (μm) mesh. The field team collected the samples starting at the downstream end of the 100-meter reach and working upstream to avoid disturbing the substrate before sampling. The team members collected macroinvertebrates by disturbing the substrate immediately in front (upstream) of the D-frame net and scrubbing the substrate with gloved hands. When the water was too deep to dislodge the invertebrates by hand, the substrate was sampled by kicking it with felt-soled wading boots. The contents of the net were emptied into 1-liter Nalgene bottles and preserved with ethanol.

A suite of ambient water-quality measurements was recorded at each site, as required by the ASCI protocols. Parameters measured included temperature in degrees Celsius (°C), dissolved oxygen (DO) measured in both milligrams per liter (mg/L) and percent saturation, specific conductivity in milliSiemens per centimeter (mS/cm), and pH. All parameters were measured using a YSI Model 556 multi-probe system. The multi-probe was serviced before the field season and was calibrated or checked with confidence solution once daily according to manufacturer's specifications.

Drift-net Sampling, 2004

One composite drift net sample was collected at each stream site in 2004. Field staff set five nets with 363-μm mesh and 12-by-18-inch openings across the stream to collect drifting organisms. The nets were positioned at the upstream end of the 100-meter-long reach to avoid disturbance from concurrent ASCI sampling.

The field team recorded the depth of the submerged portion of each net and the stream velocity at each net's mouth for use in calculating the total volume of water that flowed through the net during the sampling interval. The sampling interval was approximately 1 hour. Team members recorded the actual length of time on the field data sheets. They combined the material removed from all nets at a site in a 1-liter Nalgene bottle to obtain a single composite sample for each site.

Surber Sampling, 2005 and 2007

The use of Surber samplers was added to the study program in 2005 to determine the density and composition of macroinvertebrate populations. Surber samples were collected only in riffle/cobble habitats in order to ensure more valid comparison between samples (Parsons and Norris, 1996). The sampler was constructed of 363-μm-mesh netting with a 1-square-foot mouth. A 1-square-foot metal frame attached to the net was folded down over the substrate in front (upstream) of the net to delineate the sampling area. To collect samples, field staff placed the net with the opening facing upstream and disturbed the substrate within the frame.

Five Surber samples were collected from a selected riffle/cobble area at each sampling site. From habitat characterization completed in 2004, researchers determined that riffle/cobble habitat was available at all previously established sampling reaches scheduled for sampling in 2005 and 2007. Samplers placed each Surber sample in a separate Nalgene bottle, preserved it with ethanol, and labeled the sample with site code, date, and number in the series (e.g., 1 of 5).

Modified ASCI Sampling, 2004 and 2005

Big Wiggly and Frying Pan lakes were sampled in August 2004 and June 2005 using a modified ASCI method (Major and Barbour, 2001). The goal of this sampling was reconnaissance only, and the sampling was not intended to be a quantitative sampling of the invertebrate populations in these lakes. Proportional habitat representation in the lake was assessed, and 20 subsamples were collected from each lake with the D-frame kick net. Because there was no flowing water, the field team dragged the net through the habitat substrate. When sampling emergent vegetation, team members positioned the net under the vegetation and disturbed the vegetation to dislodge resident organisms into the net. All 20 subsamples were composited into one sample, were placed in a Nalgene bottle, and were preserved with alcohol for later processing.

15.2.5.2 Laboratory Procedures

All samples were shipped to Anchorage for processing by scientists at HDR Alaska, Inc. Samples were logged on tracking sheets with site information, date sorted, date identified, processor's initials, and quality-control information according to QA/QC procedures as described in the 2005 field sampling plan for fish and aquatic habitat (see Appendix F of this environmental baseline document).

Sorting and Subsampling

ASCI Samples, 2004, 2005, and 2007. Sample material was placed in a numbered 30-square-grid Caton subsampling tray. A computer-generated table of random numbers was used to select the numbered squares for sorting. Organisms were sorted from the sample material until at least 300 specimens were counted and the last square selected for sorting was completely processed, even if the total for the sample exceeded 300 organisms. If macroinvertebrate densities exceeded 300 organisms per square (as determined early in the sorting process), four randomly selected squares were removed from the original volume of sample material and sorted in a second tray using the same random-selection method (Major and Barbour, 2001). This approach was used to ensure complete taxa representation and accurate density calculations. The laboratory team placed all organisms picked from the sample into a vial filled with histological-grade ethanol for later identification.

Drift Samples, 2004. All organisms were separated from the drift-sample debris. If it became evident that a high density of organisms (more than 1,000) was present in the sample, subsampling was used as described above for ASCI samples. The laboratory team placed the organisms into a vial filled with histological-grade ethanol for later identification.

Surber Samples, 2005, and 2007. All organisms were separated from the Surber-sample debris and were placed into a vial filled with histological-grade ethanol for later identification.

Identification

A 40x-power dissecting microscope was used to identify the sorted and preserved organisms to genus. To identify Chironomidae larvae to genus, 10 percent of the total number of Chironomidae larvae per subsample or a minimum of 20 individuals (strictly 10 percent in 2004) were identified. In 2005, all Chironomidae in samples that contained 20 specimens or less were identified. The laboratory team mounted organisms on slides with CMC-10 mounting media and identified them using either an Olympus

Model CX41 or a Bausch and Lomb 400x compound microscope. If it was not possible to identify an organism to genus (or the identification was uncertain) because of missing identifiers or small size, this limitation was noted on the data sheets along with the lowest taxon to which the organism could be identified with certainty. Although most taxa were identified to genus, some were left at a higher taxonomic classification because of the difficulty associated with taking them to higher resolution—a common practice in many macroinvertebrate assessment projects (Ourso, 2001; Bennett, 2001; ENRI, 2002). For example, oligochaetes are often not identified to genus in macroinvertebrate assessments because there are few taxonomic specialists available to perform the identifications and because the information gained from the additional resolution is of relative inconsequence to fish or water-quality assessments. Several macroinvertebrate taxonomic keys were used in the identification process (i.e., McCafferty, 1998; Merritt and Cummins, 1996; Wiederholm, 1983; Needham and Needham, 1962). Each year, independent taxonomic verification by third-party taxonomists was performed on 10 percent of the samples or a reference collection.

15.2.5.3 Data Analysis

Several metrics described in the ASCI protocol (Major and Barbour, 2001) were calculated from the macroinvertebrate data for each site. These metrics are taxa richness; percent Ephemeroptera, Plecoptera, and Trichoptera (EPT); percent Chironomidae; percent other Diptera taxa; percent dominant taxon; and Community Tolerance Index (CTI). These metrics have been documented as indicators of habitat change in previous studies (Major and Barbour, 2001). For the analysis of Surber-sample data, results were averaged from the five samples collected at each sample site, and the standard deviation of the mean was calculated for each result and standard error was calculated for the samples. Data should be interpreted with caution, because the number of samples was small.

Taxa richness was calculated as the total number of taxa found in a sample. Taxa richness scores were generated from the lowest taxonomic classification obtained for each organism. As described above, taxa richness scores were often based on genus-level identifications; however, a few taxa (e.g., Oligochaeta) were left at lower resolution.

Percent EPT is the portion of a sample that is made up of organisms in the orders Ephemeroptera, Plecoptera, and Trichoptera. Because EPT taxa are typically sensitive to changes in water quality, the percent of EPT abundance relative to total abundance is often used to assess the degree of disturbance in a sample (Lenat, 1988; Plafkin et al., 1989). Percent EPT was calculated by dividing the number of EPT organisms in a sample by the total number of organisms in that sample.

Similarly, *percent Chironomidae* and *percent other Diptera* are the proportions of a sample represented by the Family Chironomidae and by other taxa in the order Diptera, respectively. These metrics were calculated in the same manner as described for percent EPT.

Percent dominant taxon is the proportion of the sample represented by the most abundant taxon. Percent dominant taxon was calculated for each sample by determining which taxon represented the largest number of organisms in the sample and dividing that number by the total number of organisms in the sample (Plafkin et al., 1989).

The *Community Tolerance Index* for each site was derived by weighting the established tolerance value (TV) of each taxon identified for the subsample. Regional TVs for some, but not all, taxa of aquatic

macroinvertebrates have been established in the published literature and are available in Appendix B of the Environmental Protection Agency's (EPA's) Rapid Bioassessment Protocol (Barbour et al., 1999). The CTI is therefore calculated based on the numbers of taxa with assigned TVs and not solely on the total number of taxa in the sample.

The CTI value at each station was calculated using the following formula:

$$CTI = \frac{\sum_{t1...tn}\left(N_t \times TV_t\right)}{N_s}$$

Where:

CTI = Community Tolerance Index

N_t = total number of organisms in each taxon with an assigned TV in the subsample

TV_t = tolerance value of each taxon

N_s = total number of macroinvertebrates with an assigned TV in the subsample

Weighted TVs were derived by multiplying the total number of organisms in each taxon by the taxon's TV. All weighted TVs for the station were then summed and that value was divided by the total number of macroinvertebrates in the sample with assigned TVs, resulting in the CTI for that station.

Temporal and spatial trends were analyzed using SPSS and Excel data packages. Macroinvertebrate metric data were tested for differences between drainages, between upstream and downstream sites, and from year to year using a relative significance (*P*) value of 0.05. Test procedures are described in Section 15.2.7.

15.2.6 Periphyton Methods

Detailed descriptions of field protocols for the periphyton sampling can be found in the *Draft Environmental Baseline Studies, 2005 Field Sampling Plan, Fish and Aquatic Habitat* (see Appendix F of this environmental baseline document). Periphyton sampling sites for 2004, 2005, and 2007 are listed in Table 15.2-1, and their locations are depicted on Figure 15.2-1. With the addition of ADF&G methods for periphyton collection in 2005, sampling intensity was increased at each site and frequency was decreased from twice in 2004 to once per year in 2005 and 2007.

15.2.6.1 Field Sampling Protocol

Periphyton sampling was conducted concurrently with the macroinvertebrate sampling: June 1 through 6, and August 14 through 18, 2004; June 10 through 13, 2005; and June 13 through 15, 2007. Field sampling protocols used in 2004 were geared toward collecting diatoms for identification (Barbour et al, 1999), and in 2005 and 2007 toward collecting samples to determine chlorophyll-*a* concentrations (ADF&G, 1998). As described in Section 15.2.5.1, macroinvertebrates and periphyton were sampled concurrently with two team members collecting macroinvertebrate samples, and a third member collecting periphyton samples. Generally, team members began collection at the downstream end of the stream reach and worked upstream for 100 meters. The concurrent sampling was intended to avoid disturbance of the streambed upstream of sampling.

Sampling by Modified EPA Rapid Bioassessment Protocol, 2004

Periphyton sampling methods used in 2004 were modified from the periphyton section of EPA's RBP (Barbour et al., 1999). Modifications to the protocols consisted of sampling five transects instead of four and sampling various periphyton habitats based on proportional representation (similar to ASCI protocols for macroinvertebrates) instead of sampling four riffle/run areas. These modifications improved the ability to standardize stream sampling areas for the macroinvertebrate and periphyton studies. Four periphyton habitat types were documented while performing the habitat-assessment survey: hard removable substrates (woody debris, cobble, gravel), soft removable substrates (mosses and macrophytes), large substrates (boulders, bedrock, logs), and loose substrates (sand, silt, clay).

The field team collected 20 periphyton subsamples from the stream reach at each site and combined them to form one composite sample per site. The proportion of the 20 subsamples collected from each of the four habitat types was based on the percentage of each habitat that existed in the stream reach (as described for macroinvertebrates). Sampling procedures varied depending on the habitat being sampled, as described below. For QA/QC purposes, duplicate samples were collected at 10 percent or more of the sites during each sampling event.

To sample hard removable substrates, cobbles and/or gravel and/or pieces of wood were removed from the stream and placed in a bucket. Each piece removed constituted one of the 20 subsamples. On the stream bank, a rubber sampling band was wrapped around the cobble or gravel with the hole in the band located on the upper surface of the cobble or gravel. The sampling bands were created prior to the first sampling event by cutting a 4.5-centimeter-diameter hole in a bicycle-tire tube and reinforcing the opening with a rubber washer to prevent stretching or tearing. The exposed area of the rock was scrubbed with a small toothbrush, and the loosened material was rinsed into a pan. The pan was then drained into the 1-liter Nalgene bottle containing the composite sample.

When mosses and macrophytes were sampled, approximately 16 square centimeters of material was collected from the stream and was placed in an empty 1-liter Nalgene bottle. The material was rinsed with a small amount of water and the bottle was shaken vigorously to dislodge periphyton from the plant material. The rinse water containing periphyton was transferred to the 1-liter Nalgene sample bottle containing the composite sample.

Large substrates were sampled in situ with a 4.5-centimeter-diameter sampling tube of polyvinyl chloride (PVC) and a toothbrush with a head that was modified to fit inside the PVC tube. Foam lining was attached to the PVC tube to create a "seal" when pressed against the large substrate. This assembly isolated a 4.5-centimeter sample area on the boulder or other large substrate from the stream flow. The modified toothbrush was used to scrub the surface of the substrate inside the PVC tube to dislodge the periphyton. The sample area inside the tube was washed with a small amount of water, and a turkey baster was used to draw out the rinse water containing the periphyton for transfer to the composite sample bottle.

Loose sediments (sand and soft sediments) were sampled with 4.5-centimeter-diameter plastic Petri dishes. The open side of the Petri dish was pushed into the substrate and a flat metal spatula was slid under the Petri dish and used to lift the dish and sample out of the water. The substrate was then removed from the Petri dish and placed in an empty 1-liter bottle. A field team member placed a small amount of water in the bottle, capped the bottle, and shook the material vigorously to dislodge the periphyton. Only

a few seconds were allowed for the sediment to settle before the rinse water containing the periphyton was transferred into the composite sample bottle.

At the end of the collection process at each site, a 1-liter Nalgene bottle marked with 100-milliliter increments contained the composite sample, which consisted of water-and-periphyton rinsate from all 20 subsamples. Enough ambient stream water was added to bring the volume to the next calibrated marker on the bottle, and this volume was recorded on the data sheet. The composite sample was shaken vigorously for 1 minute. Immediately after the composite bottle was shaken, enough water was drawn out to fill a 100-milliliter Nalgene bottle, to which two to three drops of Lugol's solution were added as a preservative. The remaining sample volume was discarded. The 100-milliliter bottles were stored in coolers and were transported to Anchorage by the field team.

Sampling by ADF&G Chlorophyll-a Method, 2005 and 2007

Periphyton samples were collected from the same riffle/cobble area in the stream reach from which the macroinvertebrate samples were collected by Surber sampler. Care was taken to avoid substrate disturbance in the area being sampled by the other team members. Periphyton was removed from 10 cobbles selected from a riffle/cobble area that had not been disturbed by macroinvertebrate sampling.

Sample collection followed ADF&G methods (ADF&G, 1998). A piece of 5-square-centimeter high-density foam was placed on a cobble. After using a toothbrush to scrub the portions of the cobble not covered by foam, all material was washed from around the foam. A clean toothbrush was used to clean the area under the foam square, and the loosened material was rinsed onto a 45-micrometer glass fiber filter attached to a hand vacuum pump. To the extent possible, water was extracted and 1 milliliter of saturated magnesium carbonate ($MgCO_3$) solution was added to the filter as a preservative. The dry filter was wrapped in a larger filter to absorb additional water, and the sample was placed it in a zipper-seal bag with silica gel desiccant. Filters were frozen in a lightproof container with desiccant for shipment to Anchorage in care of the HDR field team.

15.2.6.2 Laboratory Procedures

Diatom Sample Processing, 2004

Periphyton samples collected in 2004 using the EPA RBP method (Barbour et al., 1999) were processed by HDR scientists at Alaska Pacific University facilities. All samples were logged on a tracking sheet and a data-processing sheet.

Acid Digestion. Two 400-milliliter graduated beakers were labeled for each sample. Each sample was then transferred to a beaker. After recording the sample volume, the sample was homogenized with a hand-held blender to thoroughly mix the material and break down large periphyton colonies. The blender and the walls of the beaker were washed with deionized (DI) water into the rinsate. The new volume was recorded as the "working volume."

The beaker was then placed on a stirring plate. While the sample was being stirred, 20 milliliters of the sample were withdrawn and placed in a second, labeled 400-milliliter beaker for acid digestion. The remaining material was returned to the original sample bottle for storage.

Samples were digested using 30 milliliters of nitric acid. The beaker was allowed to heat on a hot plate set at 200ºC for two hours. After digestion was complete, a small amount of potassium dichromate was added to the sample to catalyze the reaction. The beaker was allowed to cool.

After completion of the acid digestion, several contributions of DI water were added to slightly increase the pH. The samples were left undisturbed for 12 hours while the diatoms settled in the bottom of the beaker. After the diatoms had settled, the sample was diluted using DI water until the sample pH increased to at least 6.0. Approximately 25 to 50 milliliters of sample were transferred to a 100-milliliter storage vial. This volume was recorded as the diatom volume "after digestion" (Barbour et al., 1999).

Slide Preparation. After all samples were acid digested, the diatoms were mounted on slides for identification. An initial cover slip was prepared with 10 milliliters of sample water. After the cover slip was dry, the slide was examined with an Olympus CX41 compound microscope under 400x magnification to determine whether the prepared sample had the proper distribution and density of diatoms. If the density of diatoms was too great, a new cover slip was created with less sample material, and the new volume was recorded. If the density was too thin, more sample was added. The volume of material added to the cover slip was recorded as "drip additional." Some of the slips were remade because of large amounts of sand and silt in the samples.

Naphrax was used for mounting diatom samples to slides. A cover slip with the sample was placed sample-side down on the Naphrax and heated to affix the cover slip to the slide. Slides were labeled with the sample identification code (Barbour et al., 1999).

Identification. Samples mounted on slides by HDR scientists were sent to Scott Rollins of the Michigan State University Algal Ecology Laboratory for identification. Diatom counting and identification began in one corner of each slide and continued along a transect until 600 diatoms were identified on that slide.

Chlorophyll-*a *Sample Processing, 2005 and 2007

Frozen periphyton samples were shipped from Anchorage to Bill Morris of the Alaska Department of Natural Resources, Office of Habitat Management and Permitting, in Fairbanks for chlorophyll-*a* analysis. Samples were analyzed with a Shimadzu UVI 601 spectrophotometer. Each sample was inspected and the general condition recorded before sample preparation. The sample filter was cut into small pieces and placed in a 15-milliliter centrifuge tube. Chlorophyll was extracted by adding 10 milliliters of a 90-percent solution of spectrophotometric-grade acetone and soaking overnight inside a dark refrigerator. Vials were wrapped in aluminum foil to ensure they remained completely dark during the extraction. On the day following initial preparation, samples were placed in a centrifuge and spun at 1,600 revolutions per minute for 20 minutes. The samples were decanted individually into cuvettes, and absorption values at 750 nanometers, 664 nanometers, 647 nanometers, and 630 nanometers were recorded. Approximately 0.08 milliliter of 0.1 N hydrochloric acid (HCl) was added to each cuvette, and the samples were allowed to sit in the dark for 90 seconds. Absorption values at 750 and 665 nanometers were recorded (McLean, pers. comm., 2005).

15.2.6.3 Data Analysis

Periphyton results from 2004 and 2005/2007 were analyzed in separate data sets because of differences in sample-collection and processing methods. The EPA RBP method used during the two sampling events in

2004 was designed to gather information on diatom diversity. The ADF&G chlorophyll-*a* method used during the 2005 and 2007 sampling events was designed to determine concentrations of chlorophyll-*a*.

Diatoms

Taxa richness and percent dominant taxon were calculated from the 2004 diatom data. Because only one year of data was collected, analysis of the data was limited to an examination of spatial variability among sample sites.

Taxa richness was calculated as the total number of taxa, usually genera, identified in a sample. Researchers identified 600 diatoms from each slide-mounted sample to the lowest taxon practicable, and from this list, the sum of all taxa for that station was calculated.

Percent dominant taxon is the portion of the sample represented by the most populous taxon. Percent dominant taxon was calculated for each station by determining which taxon represented the largest number of organisms in the sample and dividing the number of organisms of that taxon by the total number of organisms in the sample.

***Chlorophyll*-a**

The ADF&G-preferred method for analyzing periphyton abundance is to determine chlorophyll-*a* concentrations (ADF&G, 1998). Chlorophyll-*a* was reported as milligrams per square meter (mg/m^2). A correction factor was sometimes necessary to account for conversion from chlorophyll-*a* to phaeophyton. This correction factor was applied to the data set as necessary. Temporal and spatial analyses were possible with 2 years of data (2005 and 2007), but results should be interpreted with caution because the number of samples was small.

15.2.7 Results and Discussion

15.2.7.1 Macroinvertebrates

During the course of the program, 132 primary macroinvertebrate samples, plus duplicates on a minimum frequency of 10 percent, were collected at the established biological monitoring sites in the mine study area. Other opportunistic samples were collected during ancillary studies and are reported elsewhere in the EBD (see Fish Resources Section XX and Appendix B, Iliamna Lake Study). Two hundred thirty five macroinvertebrate taxa, including 64 chironomid taxa, have been identified in the Bristol Bay drainages study area (Tables 15.2-2 and 15.2-3). (The Bristol Bay drainages study area includes both the mine and the transportation-corridor study areas, the latter of which is discussed in Section 15.4). Differences in taxa richness occurred between years at sites in the mine study area (e.g., NK100C and UT100D) and between sampling methodologies (Figure 15.2-2 and 15.2-3). At many sampling sites, however, differences were minimal. A combination of modifications to the sampling strategy and naturally occurring seasonal and annual variability could account for the differences between years both in taxa richness and in the types of taxa identified.

As mentioned above, sampling strategies were different in 2004 than in 2005 and 2007, and the number of sampling sites was reduced from 20 in 2004 to eight in 2005, then increased to 10 in 2007. In addition, samples were collected during early and late summer in 2004, whereas samples were collected only in

early summer in subsequent years. Seasonal variability in macroinvertebrate communities is well documented (HDR, 1999; Major et al., 2000, Merritt and Cummins, 1996) and is somewhat evident in Figure 15.2-2. Taxa richness in 2007 was comparable to 2004 levels.

Analysis of data from 2004 indicated that benthic sampling using a kick net (ASCI method) was generally more successful at collecting a variety of macroinvertebrates than the drift-net method of sampling the water column (Figure 15.2-2). The only instances where drift sampling collected equal or greater numbers of taxa than ASCI sampling were in June at CR199A, SK100C, UT100B, and UT119A. Drift sampling was discontinued after 2004 because, generally, fewer organisms were collected by that method than by using kick nets.

Macroinvertebrate metrics were calculated based on the 2004, 2005, and 2007 data for ASCI and Surber samples (Tables 15.2-4 through 15.2-9). Diptera, including the Family Chironomidae, was generally the dominant taxon, and Ephemeroptera typically made up the bulk of EPT taxa (Figures 15.2-4 and 15.2-5). In bioassessment studies in the Lower 48, a high proportion of Chironomidae in the population and/or a high value for percent dominant taxon indicate a more stressful aquatic habitat for macroinvertebrate survival (Barbour et al., 1999); however, conditions in the mine study area are pristine, and high numbers of Chironomidae are considered normal for this region and elsewhere in Alaska (Oswood et al., 1995).

Total taxa richness was lower in 2005 than in 2007 (Figure 15.2-3). Average percent EPT (sensitive taxa) was generally higher for samples collected using the Surber method (riffle/cobble habitat sampling) than percent EPT in ASCI-method samples (multi-habitat sampling) in the mine study area (Tables 15.2-6 through 15.2-9), despite the fact that riffle/cobble habitat composed the largest portion of habitats sampled by the ASCI method.

CTI values are another measure of relative aquatic habitat quality and are based on the relative tolerance of macroinvertebrate taxa to stressful conditions. CTI scores in 2004, 2005, and 2007 ranged from 3.9 through 6.1, 4.9 through 6.0, and 4.5 through 6.6, respectively (Tables 15.2-4 through 15.2-9; possible range of values 0 through 10). ASCI samples produced a wider range of CTI values than Surber samples in both 2005 and 2007 (Tables 15.2-6 through 15.2-9).

To test for temporal and spatial trends in the metric data, Surber-sample data from 2005 and 2007 for the five sites that were consistently sampled in those years—NK100A, NK100C, SK100B, UT100B, and UT100D—were analyzed. For each response variable, a repeated-measures analysis of variance (ANOVA) was performed using Proc Mixed for SPSS with a compound symmetry covariance structure. Each location in each year was considered a subject, and year and river were factors. Response variables that were proportions were first arcsine transformed using the formula 2*arcsine (square root(y)) to equalize the variance, and proportions of zero were converted to 1/(4*n) prior to applying the transformation (Neter et al., 1990). Statistically significant differences were found among rivers for percent Ephemeroptera, percent Diptera, percent other order, and percent EPT taxa (Table 15.2-10). This result would be expected because habitats are quite different between the Upper Talarik and the Koktuli drainages.

To test for differences between upstream sites and downstream sites in the ASCI data, results from two sites each on the Upper Talarik (UT100D and UT100B) and on the North Fork Koktuli (NK100C and NK100A) were compared using a paired t-test. The South Fork Koktuli was not analyzed because only one site (SK100B) was sampled during all years. The sample size for each site was three (2004, 2005, and

2007). Proportions were arcsine transformed before analysis. There were statistically significant differences in percent Ephemeroptera, percent Chironomidae, and percent Diptera between upstream and downstream sites on the Upper Talarik and in percent Chironomidae and percent Diptera between upstream and downstream sites on the North Fork Koktuli (Table 15.2-11).

Differences between upstream sites and downstream sites in the Surber data were tested with repeated-measures ANOVAs for each river separately. Each site in each year (2005 and 2007) was used as a subject with the five Surber samples as a repeated measure. SiteID was the only factor included in the model. Proportions were arcsine transformed before analysis. No statistically significant differences were found between upstream and downstream locations for Surber samples in any of the response variables for either river (Table 15.2-12). The difference between these results and the results from the ASCI tests could be due to one less year of data for Surber sampling or there may be fewer differences among riffle habitats that among more varied habitats.

Water-quality results (Tables 15.2-13 through 15.2-16) were comparable to typical Alaskan cold-water streams (Brabets and Ourso, 2006). It should be noted that results for percent DO indicate frequent supersaturated conditions (i.e., results higher than 100 percent). Supersaturation of DO is not uncommon and occurs as a result of a combination of factors: temperature, atmospheric pressure, turbulence, and production of oxygen during photosynthesis in aquatic plants. Turbulence in shallow water (streams) and oxygen from photosynthesis (lakes) are the most likely contributing factors to DO supersaturation in the mine study area. To evaluate the possibility of instrument error causing the highest readings, the highest percent DO values were recalculated and were compared to values calculated from DO concentrations measured at the same sampling sites during the same months by the water-quality sampling team. The results of these cross-checks indicate that DO supersaturation was indeed occurring, although the meter readings collected in the field tended to be slightly higher (2 to 3 percent) than calculated values. This could be the result of slight instrument error. Data are not presented for instances when an obvious instrument malfunction occurred (e.g., June 2005, see Table 15.2-15). In general, at the time of sampling, all three drainages provided good to optimal levels of DO, temperature, dissolved constituents (conductivity), and pH—water-quality parameters that are important to diverse macroinvertebrate communities.

Water-quality results were compared to total taxa and percent EPT metrics for both Surber and ASCI samples using the statistical procedures described above in the macroinvertebrate discussion. For Surber samples, the repeated-measures ANOVAs used total taxa and percent EPT as response variables and separate tests were conducted for each explanatory variable: DO as milligrams per liter, DO as percent, specific conductivity, relative conductivity, pH, and temperature. Percent EPT was arcsine transformed before analyses.

Contrary to what was expected, percent EPT declined with increasing DO as mg/L (Table 15.2-17); however, if SK100B was removed from the analysis, the relationship between DO as mg/L and percent EPT was no longer significant ($P = 0.119$). SK100B had low pH and temperature, and low percent EPT, a relationship that might be expected because low pH can sometimes have a detrimental effect on the sensitive EPT taxa. When river (NK, SK, UT) was included in the model as a categorical variable, no water-quality variables showed statistically significant relationships with total taxa or percent EPT (all $P > 0.050$), although DO as mg/L was close to significant for percent EPT ($P = 0.051$).

For ASCI samples, simple linear regression was used to evaluate the response of total taxa and percent EPT to changes in DO as mg/L, DO as percent, specific conductivity, relative conductivity, pH, and temperature. Percent EPT was arcsine transformed before analysis.

The taxonomic richness of ASCI samples declined an average of 0.799 taxa for every 1°C increase in temperature, a result which is statistically significant (Table 15.2-18). When river (NK, SK, UT) was included in the model as a categorical variable, temperature was still the only significant ($P = 0.036$) water-quality variable for total taxa, and no water-quality variables were significant with percent EPT (all $P > 0.05$).

Measurements of habitat parameters at each site fall within ranges considered good to optimal for aquatic habitat (Table 15.2-19; Major and Barbour, 2001). The sites sampled in this study were located in a pristine area with few to no human-caused effects.

15.2.7.2 Periphyton

Thirty-six diatom genera and 188 diatom species were present in the 20 samples collected in 2004 in the Bristol Bay drainages study area (Table 15.2-20). (The Bristol Bay drainages study area includes both the mine and transportation-corridor study areas, the latter of which is discussed in Section 15.4.) During the course of the study, 115 primary periphyton samples were collected from the mine site study area biological monitoring sites.

Taxa richness and percent dominant taxon were calculated for periphyton collected in 2004 (Table 15.2-21). The metrics using the 2004 data were calculated from identifications of periphyton genera. Taxa richness was relatively uniform among the sites sampled in 2004, with seasonal differences of four or fewer taxa at each site, except at SK100B, which had a difference of seven taxa (Figure 15.2-6 and Table 15.2-21). The percent dominant taxon in periphyton samples in some instances equaled more than 50 percent, which result is generally considered a negative indicator for stream health (Wehr and Sheath, 2003). However, the stream reaches sampled are considered representative of unimpaired conditions because they are pristine and in a region of negligible human effect. As stated in the macroinvertebrate section above, measurements of water-quality parameters consistently fell within ranges considered good to optimal for aquatic habitat health (Table 15.2-19).

Periphyton samples collected in 2005 and 2007 were analyzed for chlorophyll-*a* concentration as a quantifiable measure of productivity. In 2005, samples were collected from six sites, and in 2007, samples were collected from 10 sites; 10 samples were collected from each site. Samples from UT100D in 2005 were potentially compromised by insufficient freezing time for sample preservation. Data still could be extracted from these samples and are reported in this document, although the usability of those data is in question.

Average chlorophyll-*a* concentrations from samples collected in 2005 ranged from a low of 2.1 ±0.82 mg/m^2 at UT100D to a high of 17.0 mg/m^2 at SK100B (Table 15.2-21; Figure 15.2-7). Variability among the five samples collected at each site was relatively high and was particularly notable at SK100B, UT100B, and UT138A. Chlorophyll-*a* concentrations from samples collected in 2007 ranged from 2.3 mg/m^2 at UT119A to a high of 30.2 mg/m^2 at UT100D (Table 15.2-21; Figure 15.2-7). No consistent temporal trends could be found in the chlorophyll data between the 2005 and 2007 sampling events. Chlorophyll-*a* concentrations in 2007 were similar to concentrations found in 2005 except at two of the

sites—concentrations at UT100D were much higher in 2007 than in 2005, and concentrations at SK100B were much lower in 2007 than in 2005. A possible explanation for the wide difference at UT100D is that the previously described sample preservation issues associated with UT100D in 2005 may have affected the results for that site for that year. Periphyton growth is correlated with nutrient availability, photoperiod, and temperature, and it is possible that differences in habitat parameters from year to year produce variability in periphyton data. Temperatures in 2007 were generally cooler than those in 2005, and this difference could explain the lower chlorophyll-*a* concentrations at SK100B in 2007; however, the lower chlorophyll concentrations in 2007 were not seen at the other sites.

No consistent trend was found between macroinvertebrate taxa richness or percent EPT and chlorophyll-*a* concentrations. However, Chironomidae often comprised a high percentage of the taxa composition at a given site and, in many cases, was the dominant taxon comprising over 50 percent of the sample. Some Chironomidae genera feed on periphyton or prey on taxa that consume periphyton. In 2005, percent Chironomidae was found to be highly correlated with chlorophyll-*a* concentrations ($R^2 = 0.7908$), but this trend was not as evident in 2007 ($R^2 = 0.1157$; Figure 15.2-8).

15.2.8 Summary

Twenty sites in the mine study area were sampled in 2004 for macroinvertebrates and periphyton. During the course of the study, 132 primary macroinvertebrate samples and 115 primary periphyton samples were collected at the mine site biological monitoring sites; additional duplicate samples were collected on approximately 10 percent frequency and other opportunistic samples were collected for ancillary studies or reconnaissance purposes. Of the 21 sites, eight (five in the immediate vicinity of the deposit) were selected for continued sampling in 2005, and 10 were sampled in 2007. The sampling sites included a range of stream sizes and habitats, as well as two sites at lakes. Methods used to sample macroinvertebrates and periphyton differed slightly between 2004 and subsequent sampling years of 2005 and 2007. Beginning in 2005, Surber sampling for macroinvertebrates replaced drift-net sampling in streams, and collection of periphyton samples for analysis of chlorophyll-*a* concentrations replaced sampling by the modified EPA RBP method. ASCI sampling was consistent throughout all 2004, 2005, and 2007 events.

Aquatic-habitat surveys indicate that the sample sites were composed largely of riffle/cobble habitat, which is the preferred habitat of Ephemeroptera, Plecoptera, and Trichoptera taxa. The EPT taxa are the most likely to be used as indicators of the quality of aquatic habitats pre- and post-mine development. The results of the metrics generally indicate low percent EPT, high percent Chironomidae, and high percent dominant taxon, which can sometimes be negative indicators for stream health, although similar results have often been seen in other bioassessment studies in Alaska (ADF&G 2007). No statistically significant relationship was found between most water-quality results and the macroinvertebrate metrics data, but taxa richness in ASCI samples was negatively correlated with temperature, a result that was expected.

A range of macroinvertebrate and periphyton sample-collection methods was employed during the beginning stages of this project to determine which methods would work best in these systems. The variety of methods used contributes greatly to the robustness of the baseline data-collection program.

15.2.10 Glossary

Acid digestion—process by which organic material is separated from inorganic material under low pH conditions.

Diatom—microscopic algae with cells that have two separate halves and walls made of silicon.

Epifaunal substrate—material on a streambed used by organisms that live on the bottom of the stream.

Macroinvertebrates—organisms with no backbone and that are large enough to be seen without the aid of a microscope.

Macrophytes—plants living in lakes, streams, or wetlands and that are large enough to be visible with the naked eye.

Metrics—standards of measurement.

Phaeophyton—a product of chlorophyll degradation that absorbs light at the same wavelength, thereby interfering with measurement of chlorophyll.

Periphyton—micro-algae that attaches to rocks or other solid surfaces.

Taxon (plural: taxa)—a taxonomic category or group, such as a phylum, order, family, genus or species.

Notes:

a. Note that percent dominant taxon is calculated based on genera, whereas Chironomidae and other metrics are based on family-level taxonomic identifications and, therefore, may not match the percent dominant taxon.

b. Includes Chironomidae genera.

— = Samples were not collected.

TABLE 15.2-6
Macroinvertebrate Metrics for Data Collected Using the ASCI Method, Mine Study Area, June 2005

Site ID	Taxa Richness [a]	Percent EPT	Percent Chironomidae	Percent Other Diptera	Percent Dominant Taxon [b]	CTI
NK100A	22	12	76	7	76	5.5
NK100C	20	26	47	25	47	4.9
SK100B	18	7	90	1	90	5.8
UT100B	17	15	39	46	45	5.7

15.3 Fish—Transportation Corridor Studies

15.3.1 Introduction

Development of the Pebble Deposit would likely require the construction of an approximately 90-mile (144-kilometer) access road linking the Pebble Deposit to Cook Inlet. To address this possibility, Northern Dynasty Mines, Inc. (NDM), the Pebble Partnership, and the Alaska Department of Transportation and Public Facilities have considered several possible road alignments. This study characterizes typical conditions within the transportation corridor study area by focusing on one representative road alignment**.** Along this route, there are numerous watersheds varying from large rivers (e.g., Newhalen River) to very small, seasonally flowing channels, each of which belongs to one of two major drainage basins: Bristol Bay or Cook Inlet. This chapter section focuses on only those watersheds associated with the Bristol Bay Basin. Watersheds associated with Cook Inlet are addressed in Chapter 40, Section 40.1.

The survey sites selected for this study include primary survey sites located directly on or near the representative road alignment. Each of the primary survey sites corresponds to a milepost along the representative road alignment. Mileposts represent the distance along the representative road alignment between the road alignment's western terminus at the edge of the Pebble Deposit and the primary survey site locations. The naming convention for mileposts consists of "MP" (for "milepost") followed by a number that specifies the distance in miles between the Pebble Deposit and the site location. Additionally, there are support survey sites that are located upstream and/or downstream of the primary survey sites, or on nearby tributaries. Primary sites are regarded as representative of possible stream crossing conditions throughout the study area, and support survey sites provide additional information regarding fish resources at nearby locations in the same watershed. Primary and support survey sites were identified and subsequently surveyed for fish and aquatic habitat conditions (Figure 15.3-1).

This section presents a summary of the study objectives, methods, and results of the transportation corridor fish and aquatic habitat surveys that were conducted in the Bristol Bay Basin from 2004 through 2008. The primary survey sites within the Bristol Bay Basin have been grouped into one of eight watershed groups: Upper Talarik (UT), Newhalen, Isolated Watersheds, Roadhouse/Northeast Bay/Eagle Bay, Youngs/Chekok/ Canyon, Knutson Bay/Pedro Bay, Pile Bay/Lonesome Bay, and Iliamna River (Figure 15.3-2; Table 15.3-1). Within each watershed group, data from the primary survey sites are summarized by watershed. When additional data from support survey sites elsewhere in these watersheds are available, these data are discussed in reference to the nearest primary survey site within the same watershed (Table 15.3-1).

This section also includes two appendices that describe data collected at each survey site during the transportation corridor studies from 2004 through 2008:

- Appendix 15.3A, Transportation Corridor, Bristol Bay Basin Survey Data Summaries: Primary Survey Sites - Data Collected on or near Possible Representative Road Alignment Stream Crossings
- Appendix 15.3B, Transportation Corridor, Bristol Bay Basin Survey Data Summaries: Support Survey Sites - Data Collected Upstream or Downstream of Surveyed Primary Survey Sites

Appendices 15.3A and 15.3B are organized in ascending order of mileposts, from west to east, along the representative road alignment. Appendix 15.3A presents data from primary survey sites located on or near possible stream crossings of the representative road alignment. Appendix 15.3B presents data from support survey sites that are located upstream and/or downstream of primary survey sites that were actually surveyed.

A brief description of watershed characteristics and processes influencing the nature and condition of fish habitat and other aquatic resources in the Bristol Bay area, as well as a general description of the Bristol Bay sport and commercial fisheries, is provided in Chapter 15, Section 15.1. Details on specific watershed characteristics in the Pebble Project study area, including climate, geology, phsyiography, soils, hydrology, and vegetation, are provided in companion studies described in the Pebble Project Environmental Baseline Document (EBD) Chapters 2, 3, 4, 5, 7, and 13, respectively.

15.3.2 Study Objectives

The overall goal of the transportation corridor fish and aquatic resource studies was to describe the baseline characteristics of fish assemblages and aquatic habitats representative of possible stream crossing locations along a representative road alignment. Baseline conditions refer to the habitats and associated fish populations as they currently exist in the watersheds in the absence of any road development. The studies, in combination with resource investigations described in other EBD chapters, were collectively designed to address the following technical questions:

- What are the baseline channel conditions at each primary and support survey site?
- What types of aquatic habitats are present at each primary and support survey site, and how can those habitats be described?
- What are the water quality characteristics at each primary and support survey site?
- What is the composition and distribution of fish species at each primary and support survey site?

15.3.3 Study Area

The Bristol Bay Drainages study area for the transportation corridor fish and aquatic resource surveys consisted of a 2,000-foot (600-meter) wide survey corridor encompassing the representative road alignment, beginning at the northeastern edge of the Pebble Deposit and continuing east to the Chigmit Mountains (Figure 15.3-1). Within the Bristol Bay Basin, the representative road alignment traverses several rivers, streams, and lake outlet channels at 73 different locations. These representative crossing locations are within several different watersheds, including Upper Talarik Creek, Newhalen River, Negro Lake, an unnamed lake in the vicinity of Bear Creek, Roadhouse Creek, an unnamed tributary to Eagle Bay, Eagle Bay Creek, Youngs Creek, Chekok Creek, Canyon Creek, several unnamed tributaries to Knutson Bay, Knutson Creek, an unnamed tributary to Pedro Bay, two unnamed tributaries to Lonesome Bay, Pile River, Iliamna River, and Chinkelyes Creek. Most of these watersheds eventually drain to Iliamna Lake. The exceptions are the isolated watersheds of Negro Lake and the unnamed lake near Bear Creek, where precipitation, evaporation and groundwater exchange, rather than surface water flow, appear to be the dominant hydrologic processes. From Iliamna Lake, water flows for 143 miles (369 kilometers) via the Kvichak River into Bristol Bay. The Kvichak River subbasin is one of nine major river basins draining Southwest Alaska into Bristol Bay. Fifty-five of the 73 representative stream crossings were

surveyed as primary survey sites along the representative road alignment in 2004 through 2008 (Table 15.3-1). The remaining 18 primary survey sites on or near these representative stream crossings were not surveyed during this study period, due to local access constraints.

15.3.4 Scope of Work

Fish and aquatic resource surveys within the transportation corridor study area were initiated in 2004 by NDM and were continued by the Pebble Partnership through 2008. Field studies were carried out by HDR Alaska, Inc. (HDR) from 2004 through 2007 and by R2 Resource Consultants, Inc. (R2) in 2008. Consistent with the study objectives, there were four main study components: channel morphology, aquatic habitat characterization, water quality, and fish distribution.

15.3.5 Methods

Fish abundance and habitat surveys in the Bristol Bay drainages study area were conducted in 2004, 2005, 2007, and 2008. Over the study period, fish presence and habitat surveys were conducted at 55 primary survey sites (Appendix15.3A) and 42 related support survey sites (Appendix 15.3B) (Table 15.3-1). Detailed methods for the aquatic habitat and fish resource studies are described in Appendix E of this EBD. Included here is a brief summary of these methods as they relate to survey site selection, aquatic habitat assessments, water quality sampling, and fish distribution surveys.

Similar survey protocols and methods were used at the primary and support survey sites. Primary and support survey sites were identified remotely via a combination of topographic maps and aerial photography and were subsequently visited to determine if there was a wetted, ephemeral, or dry channel present at the site, or if there was no channel present. Photographs to document channel conditions were taken at the time of visit, and actual survey locations were documented in the field using global positioning system (GPS) units to record coordinate data. For wetted and ephemeral channels, the length of stream sampled at each survey site was 656 feet (200 meters) or 40 times the average bed width, whichever was the lesser of the two values. However, on occasion, survey lengths were greater than this in order to obtain a more comprehensive sample.

15.3.5.1 Aquatic Habitat Assessments

The overall objective of the aquatic habitat assessments was to characterize the type (e.g., pools, riffles, runs/glides, etc.), distribution, and amount of habitat available for fish at each primary and support survey site. To address this objective, aquatic habitat surveys were conducted, with each year's effort focused on specific survey sites, habitat components, or various data gaps. The majority of habitat surveys used modified Tier 1 and Tier 3 habitat survey protocols adapted from Chapter 20 of the United States Forest Service (USFS) FSH 2009–Aquatic Habitat Management Handbook (R-10 Amendment 2090.21-2001-1), *Fish and Aquatic Stream Habitat Survey* (USFS, 2001). This method allows for habitat data collection at multiple tiers (Tiers 1, 2, and 3), with Tier 1 representing the broadest level of classification (e.g., reach-scale), and Tiers 2 and 3 finer levels of classification (e.g., meso- and microhabitat units).

Modified Tier 1 protocols (USFS, 2001) were used to collect information on channel morphology and valley form at each primary and support survey site. Channel morphometry data, such as bankfull width, bankfull depth, bed width, wetted width, and gradient, were collected at transects located within each

survey site. Data collected at these transects are summarized by watershed group in the *Channel Morphology* sections of Section 15.3.6.

Modified Tier 3 habitat surveys (USFS, 2001) were conducted at each primary and support survey site where water was present to document and characterize individual habitat types available to fish (e.g., beaver pond complexes, backwaters/sloughs, pools, runs/glides, riffles, and cascades). Percent habitat composition of each site was determined by calculating the percent of the total wetted area of the site (wetted width multiplied by length) attributed to each habitat type encountered. Habitat composition was scaled up to the watershed group level by summing total wetted areas across represented habitat types divided by the total wetted area surveyed within the watershed. In addition to habitat composition data, locations of special habitat features (e.g., tributaries, springs, seeps, and possible barriers to fish migration) were also recorded in 2008. For tributaries, seeps, and springs, the percent flow contribution to the mainstem was visually estimated, and water temperatures were measured. Habitat survey activities are shown in Photo 15.3-1. Aquatic habitat data are summarized by watershed group in the *Aquatic Habitat* sections of Section 15.3.6.

15.3.5.2 Water Quality Measurements

Several water quality parameters that impact aquatic life were measured during the aquatic habitat assessment, including field measurements of surface water temperature, pH, dissolved oxygen (DO), and specific conductivity. Alaska Department of Environmental Conservation (ADEC) standards for the growth and propagation of fish, shellfish, other aquatic life, and wildlife (ADEC water quality standards for aquatic life) were compared to parameters that were measured during the 2004 through 2008 studies as provided in Table 15.3-2 (ADEC, 2009).

15.3.5.3 Fish Distribution Studies

The main survey method for assessing the presence and relative abundance of stream-dwelling fish was via direct underwater observation using snorkeling. Other methods, such as electrofishing and minnow trapping, were used when survey conditions were not conducive to snorkeling, e.g., in deep, fast, or turbid water. Various fish sampling techniques applied during the fish studies are shown in Photo 15.3-2. To the extent possible, all fish observed and/or captured were identified to species. Fork length was estimated or measured for observed and captured fish, respectively.

15.3.6 Results and Discussion

During the study period, 55 primary survey sites and 42 supporting sites were surveyed (Table 15.3-1). To facilitate the characterization of these survey sites, we have grouped survey sites into the following eight watershed groups: UT, Newhalen, Isolated Watersheds, Roadhouse/Northeast Bay/Eagle Bay, Youngs/Chekok/Canyon, Knutson Bay/Pedro Bay, Pile Bay/Lonesome Bay, and Iliamna River (Figure 15.3-2). Watershed descriptions and results specific to each of these watershed groups are provided in the sections that follow.

15.3.6.1 Upper Talarik Watershed Group

The representative road alignment crosses the upper portion of the UT watershed, near the Pebble Deposit (Figure 15.3-1). Nine primary survey sites and 11 support survey sites were identified and surveyed along

the representative road alignment within the UT Watershed Group from 2004 through 2008. Three of these primary survey sites were located in the upper UT mainstem and six were located in UT tributaries (Table 15.3-3).

The UT watershed drains an area of about 3,767 square feet (350 square kilometers) and is part of the Kvichak River system that flows into Bristol Bay. From its headwaters, located in the immediate vicinity of the Pebble Deposit (Figure 15.3-1), the stream flows in a south-southwesterly direction for about 38.5 miles (62 kilometers) where it enters Iliamna Lake. The highest elevation in the UT watershed is Pig Mountain at 2,808 feet (856 m); the lowest elevation is at the stream outlet to Iliamna Lake at 35 feet (11 meters). The watershed is bounded by a series of low, isolated mountain blocks: Koktuli Peak to the west, Groundhog Mountain to the north, Dalton Mountain to the northeast, and a long unnamed ridge that separates the UT drainage from the Newhalen River to the east. The northwestern surface water drainage divide between the NFK and UT is inconspicuous. A detailed description of aquatic habitat conditions and fish utilization in the UT watershed is provided in Section 15.1.6.3.

Channel Morphology

Channel morphology data collected at the primary survey sites indicated that the stream channels in this upper portion of the UT were both relatively narrow and shallow (Table 15.3-4), with a mean bankfull width of 14.7 feet (4.47 meters; n = 9) and a mean depth of 1 foot (0.31 meters; n = 9). The channel slopes were moderate and slightly variable with a mean gradient of 2.1 percent and ranging from 0 to 4 percent at the primary survey sites (n = 9).

Aquatic Habitat

A total length of 3,041 feet (927 meters) of stream habitat was surveyed at the nine primary survey sites in the UT. This habitat was predominantly fast-water habitat, with approximately 45 percent glide and 31 percent riffle documented (Table 15.3-5). This was consistent with results of the mesohabitat mapping and Tier 3 surveys, which indicated that the uppermost reaches of the UT were dominated by riffle and run/glide habitat types (Chapter 15, Section 15.1, Figures 15.1-71 and 15.1-73). Only one beaver pond was encountered (MP_02.6), but due to extensive wetted area, this comprised 22 percent of the total UT habitat surveyed at primary survey sites. Pools were rare and small, accounting for only 2.4 percent of the habitat surveyed.

Gravel was the dominant substrate at seven of the nine UT primary survey sites (Table 15.3-6). Two of these survey sites (MP_01.2 and MP_02.6) had predominantly smaller substrates, with approximately 75 percent silt/sand, 20 percent organics, and small percentages of gravel and cobble (Appendix 15.3A). The prevalence of gravel substrates and of riffle and run/glide habitats within the UT indicates potential for fish spawning habitat.

Special habitat features that influence fish distribution and abundance, including seeps and springs, intermittent flow reaches, and beaver dams, were recorded during surveys conducted in 2008. As mentioned above, one beaver dam was encountered at primary survey site MP_02.6. All but one of the UT primary survey sites had continuous flow when surveyed. Flow was intermittent at primary survey site MP_01.2 on UT 1.430, accounting for 1.3 percent of the total survey length in the UT Watershed Group (Table 15.3-5). Intermittent flow has been documented elsewhere in the upper UT tributaries during low-flow years. Data collected at support survey sites in the UT Watershed Group indicated that

three of these sites within UT 1.500 were dry at the time of sampling in 2005 and/or 2007 (Appendix 15.3B).

Seeps were observed at two of the UT Watershed Group primary survey sites. One seep was documented at primary survey site MP_02.3, River Kilometer (RK) 55.2 on the mainstem UT. Three seeps were observed at primary survey site MP_02.6 on UT 1.410. Seeps and springs add flow to the river, may help to moderate temperatures, stabilize flows, and thus, may offer favorable habitat refugia for fish during summer and winter low-flow periods.

Water Quality

The UT Watershed Group was characterized by water quality conditions suitable for a variety of fishes. Water temperatures were seasonably appropriate with a mean of 46.4°F (8°C) for eight primary survey sites and a range of 42.1 to 49.8°F (5.6 to 9.9°C) (Table 15.3-7). DO was saturated with a mean of 11.8 milligrams per liter (mg/L). Conductivity was low at all UT primary survey sites, ranging from 16 to 119 microSiemens per centimeter (µS/cm). Field measurements for water temperature and DO met the ADEC water quality standards for aquatic life.

The ADEC surface water temperature criteria for aquatic life in freshwater is specific to the life stage of fish present and the type of fish habitat the station represents, although surface water temperature may not exceed 68 degrees Fahrenheit (°F; 20 degrees Celsius [^{o}C]) at any time, regardless of life stages present (ADEC, 2009). Water temperatures in spawning areas and egg and fry incubation areas may not exceed 55.4°F (13°C), whereas temperatures in rearing habitats and migration corridors may not exceed 59°F (15°C; Table 15.3-2). Observed water temperatures at primary and support survey sites in the UT Watershed Group met the ADEC water temperature criteria for aquatic life (Table 15.3-7).

The mean pH was 8.6 and ranged from 7.7 to 9.7 for the UT primary survey sites (n = 8; Table 15.3-7). The ADEC maximum criterion for pH for aquatic life is 8.5 and was exceeded at four primary survey sites: MP_0.2, MP_02.6, MP_02.8, and MP_05.6 (Table 15.3-8; Figure 15.3-3; Appendix 15.3A). The pH at one site (Mini Creek) was below the ADEC minimum pH criterion for aquatic life of 6.5.

Fish Resources

Six fish species, including two anadromous salmonids, three resident salmonids, and one resident non-salmonid species, were documented at the primary survey sites in the upper UT (Table 15.3-8; Figure 15.3-4). Coho salmon were the dominant species at 89 percent (Figure 15.3-5). Other species present were Chinook salmon, Dolly Varden, sculpin, Arctic grayling, and rainbow trout. The relative abundances of these other species were low, ranging from 0.4 to 4.9 percent of total observations. Although not observed during these fish and aquatic resource surveys, adult and juvenile sockeye salmon, whitefish, and threespine stickleback have also been documented in the upper reaches of the UT during other studies in the Pebble Project study area (Chapter 15, Section 15.1.6.3, Tables 15.1-46 and 15.1-49).

Relatively few fish were observed at the primary survey sites in the UT. The three primary survey sites with the greatest number of fish and diversity of species were MP_02.3, MP_02.6, and MP_05.6 (Appendix 15.3A), which are located on the mainstem UT. The adult coho salmon observed at primary survey sites MP_2.3 and MP_05.6 were the only anadromous adult salmon observed during these surveys in the UT Watershed Group. Resident fishes were observed at multiple primary survey sites (MP_00.2,

MP_02.3, MP_02.6, MP_02.8, and MP_05.6). No fish were observed at two primary survey sites, MP_00.6 and MP_01.2. Site-specific data collected at primary and support survey sites for fish counts, life stage, and fish length are presented in Appendices 15.3A and 15.3B, respectively.

15.3.6.2Newhalen Watershed Group

This watershed group contains mainstem and tributary survey sites within the Newhalen River Watershed. The Newhalen River originates above Lake Clark and flows south for approximately 24.8 miles (40 kilometers) from the outlet of Sixmile Lake before discharging into Iliamna Lake (Figure 15.3-2). This portion of the transportation corridor study area includes primary survey sites between MP 10.9 and 19.0. The elevation of the representative road alignment within this watershed group ranges from approximately 236 feet (72 meters) at the Newhalen River to 787 feet (240 meters) at support survey site A 10.66. From 2004 to 2008, data were collected at four primary survey sites on four unnamed tributaries that enter the lower Newhalen River from the west (Table 15.3-1; Figure15.3-2). In addition, there were nine support survey sites in the Newhalen Watershed Group.

Channel Morphology

Channel morphology data indicated that the tributary channels to the Newhalen River were both relatively narrow and shallow, with a mean bankfull width of 10.5 feet (3.20 meters; n = 4) and a mean depth of 0.66 feet (0.20 meters; n = 4). Channel slopes were low to moderate, ranging from 0 to 2 percent with a mean gradient of 1.3 percent (Table.15.3-4).

Aquatic Habitat

A total length of 1,417 feet (432 meters) of stream habitat was surveyed at the four primary survey sites in the Newhalen Watershed Group (Table 15.3-5). The habitat in this watershed group was predominantly fast-water, with approximately 85 percent of the wetted surface area comprised of riffle and glide (Table 15.3-5). Pool habitat consisted of scour pools located at three primary survey sites (MP_12.2, MP_14.6, and MP_14.9) and accounted for only 15 percent of the habitat surveyed. The nine support survey sites exhibited the same dominance of habitat types; however, backwater pools were also present at A 12.577 and B 13.36a (Appendix 15.3A). All of the primary and support survey sites were located within perennial streams.

Gravel was the dominant substrate at three of the four Newhalen primary survey sites (MP_12.2, MP_14.6, and MP_17.9; Table 15.3-6). One site (MP_14.9) had cobble as the dominant substrate, with lesser amounts of gravel, sand, boulder, and organics (Appendix 15.3A). The prevalence of gravel and cobble substrates and riffle and glide habitats indicates potential for fish spawning and rearing habitat.

Large woody debris was relatively sparse throughout the Newhalen Watershed Group due to a lack of source trees in the riparian zone. No beaver ponds, seeps, or springs were documented at the primary survey sites in the Newhalen Watershed Group (Table 15.3-5).

Water Quality

The Newhalen Watershed Group was characterized by water quality conditions suitable for a variety of fishes. Water temperatures were seasonably cool and uniform across primary survey sites with a mean of

45°F (7.3°C) and a range of 43°F to 50°F (6.2°C to 9.9°C; Table 15.3-7). DO was at a saturated level, with a mean concentration of 11.7 mg/L. Specific conductivity was low and uniform, ranging from 29 to 55 µS/cm. Field measurements for water temperature and DO at all primary survey sites met the ADEC water quality standards for aquatic life.

Overall, water quality data from support survey sites within the Newhalen Watershed Group were similar to data from primary survey sites, with a few notable differences. A field measurement of water temperature at support survey site A 10.21 was 56 °F (13.2 °C; Appendix 15.3B) and thus, exceeded the maximum criterion of 13 °C for spawning and incubation areas. However, given that only non-anadromous fish species were found at this site, it is uncertain if this temperature criterion would apply to site A 10.21. In addition, DO was recorded below the ADEC minimum criterion for aquatic life at three support survey sites: B 13.36b, B 14.06, and B 14.418 (Table 15.3-8).

The mean pH for the four primary survey sites was 8.5 and ranged from 7.2 to 9.2 (Table 15.3-7). Three of the primary survey sites (MP_12.2, MP_14.6, and MP_17.9) had pH measurements that exceeded the ADEC maximum pH criterion of 8.5 for aquatic life (Table 15.3-8). One field measurement at one support survey site (A 12.577) was below the ADEC minimum pH criterion for aquatic life (Appendix 15.3B).

Fish Resources

Three fish species (one anadromous salmonid, one resident salmonid, and one resident non-salmonid species) were documented at the primary survey sites in the Newhalen Watershed Group (Figure 15.3-4; Table 15.3-9). Coho salmon were the dominant species at approximately 96 percent (Figure 15.3-6). Other species present were Arctic grayling and longnose sucker. These species each accounted for approximately 2 percent of total fish observed.

Relatively few fish were observed at the primary survey sites in the Newhalen Watershed Group. For example, there were 31 and 13 juvenile coho salmon observed at primary survey sites MP_14.6 and MP_14.9, respectively. Both Arctic grayling and longnose sucker were found at primary survey site MP_17.9, and no fish were observed at primary survey site MP_12.2 (Appendix 15.3A).

Eight of the nine support survey sites were surveyed for fish presence. A greater diversity of fish species and life stages were observed at these eight support survey sites as compared to the primary survey sites within the Newhalen River watershed. In addition to the species found at primary survey sites, sockeye salmon, Dolly Varden, sculpin, and ninespine stickleback were found at the support survey sites (Table 15.3-9; Figure 15.3-4; Appendix 15.3B). Adult and juvenile sockeye salmon and/or juvenile coho salmon were found at support survey sites A 12.577, B 13.36a, and B 13.36b. These observations extended the anadromous species distribution beyond the current Anadromous Waters Catalog locations (Figure 15.3-4; ADF&G, 2010). Juvenile coho salmon were also documented in the unnamed Newhalen T4 tributary at support survey sites A 12.577, B 13.36b, and B 13.36a.

The lower mainstem Newhalen River is known to support coho salmon, Chinook salmon, sockeye salmon, rainbow trout, and Arctic char (ADF&G, 2010; Map 15.3-3). The Newhalen River rainbow trout population includes an adfluvial component. During a separate radio telemetry study monitoring the movements and site fidelity of adult rainbow trout from the UT, tagged rainbow trout were documented overwintering in the Newhalen River (R2 Resource Consultants, unpublished data).

15.3.6.3Isolated Watershed Group

This watershed group includes two isolated watersheds that lie in the vicinity of Bear Creek (east of the Newhalen River and north/northeast of Roadhouse Creek) and drain the southwest flanks of Roadhouse Mountain. The topography in this area is relatively flat and has been influenced by relatively recent glacial activity, as evidenced by numerous kettle lakes. The isolated watersheds of Negro Lake and an unnamed lake did not appear to have a surface connection with the Newhalen River or Iliamna Lake via Roadhouse Creek, nor any other surface discharge points.

There are three primary and two support survey sites in the Isolated Watershed Group. The representative road alignment crosses one of the tributaries to Negro Lake (i.e., Negro Lake T1) at two locations (Figure 15.3-2, Table 15.3-1). These two primary survey sites range in elevation from 472 feet (144 meters) at site MP_22.5 to 521 feet at MP_23.2 (156 meters). During surveys in 2008, the upper primary survey site (MP_23.2) consisted of a dry stream channel, while no channel was located at the lower primary survey site (MP_22.5), which was also dry. Photographs of both these primary survey sites are presented in Appendix 15.3A. These data call into question the presence of a stream channel at this location as was indicated from preexisting maps. No other data were collected at these Negro Lake tributary primary survey sites. Farther east, the representative road alignment crosses one small tributary to an unnamed lake that lies southwest of the representative road alignment near Bear Creek (Figure 15.3-2, Table 15.3-1). The alignment intersects this tributary near, or perhaps even above, the headwaters that are seasonally inundated by rain events or melting snow from Roadhouse Mountain. The elevation at this primary survey site (D 22.933) is 518 feet (158 meters). D 22.933 was dry in July 2004 for a distance of approximately 1,050 feet (320 meters) downstream of the crossing location. D 22.933 was revisited in October 2007, after a period of rain. At that time, it contained flowing water (Appendix 15.3A). Only one support survey site (D 23.344) in this watershed contained flow (Appendix 15.3B).

Channel Morphology

Channel morphology parameters were measured at the only Isolated Watershed Group primary survey site (D 22.933) with flow. Primary survey site D 22.933 consisted of a small, braided flowing path of water that lacked a defined channel bed (Appendix 15.3A), so only a limited number of parameters could be measured. Flow may have developed from rain events that occurred prior to the survey period, as evidenced by submerged blueberry plants containing ripe fruit. The gradient was 1 percent and wetted width was 13.45 feet (4.1 meters; Table 15.3-4). At support survey site D 23.344, the bankfull width, wetted width, and bed width were 4.4, 2.5 and 1.0 feet (1.33, 0.77, and 0.30 meters), respectively, and the gradient was 1 percent (Appendix 15.3B).

Aquatic Habitat

At the one wetted primary survey site (D 22.933), the 279 feet (85 meters) of aquatic habitat surveyed was characterized as a flowing wetland due to the lack of a clearly defined channel. The substrate consisted entirely of organic matter, including submerged terrestrial vegetation. At support survey site D 23.344, the aquatic habitat was surveyed for 115 feet (35 meters) and was composed entirely of riffle habitat. The substrate was comprised of 50 percent organic matter and 50 percent silt. Large woody debris, overhanging vegetation, and beaver activity were absent from the Isolated Watershed Group due to a lack of source trees in the riparian zone.

Water Quality

Water quality data for the only Isolated Watershed Group primary survey site with flow (D 22.933) are presented in Table 15.3-7. Water temperature was seasonably cool at 42.6°F (5.9°C), DO was 11.2 mg/L, and specific conductivity was 30 µS/cm. The only ADEC water quality criterion for aquatic life that was not met was pH. The pH of 5.75 at D 22.933 and 5.56 at support survey site D 23.344 were below the ADEC minimum pH criterion for aquatic life of 6.5 (ADEC, 2009; Table 15.3-8; Figure 15.3-3).

Fish Resources

No fish were found during October 2007 fish sampling at Isolated Watershed Group primary and support survey sites D 22.933 and D 23.344 (Table 15.3-9). The other primary and support survey sites in this watershed group were dry, and thus were not sampled for fish. This watershed group is composed of isolated waterbodies that do not support anadromous fish species.

15.3.6.4Roadhouse/Northeast Bay/Eagle Bay Watershed Group

This watershed group includes three watersheds that drain into Iliamna Lake from Severson to Eagle Bay: Roadhouse Creek, an unnamed tributary to Eagle Bay (Eagle Bay T1), and Eagle Bay Creek (Figure 15.3-2; Table 15.3-1).

The Roadhouse Creek watershed is a low-gradient system originating at the southwest base of Roadhouse Mountain. The representative road alignment traverses the headwaters of the Roadhouse Creek watershed near the base of Roadhouse Mountain, ranging in elevation from approximately 472 to 620 feet (144 to 189 meters; Figure 15.3-2). One mainstem primary survey site (D 24.166) and six support survey sites were studied in the Roadhouse Creek watershed (Table 15.3-1).

The unnamed Eagle Bay T1 watershed drains the southern side of Roadhouse Mountain. The mainstem originates near the top of Roadhouse Mountain at approximately 2,558 feet (780 meters), where it flows south through a highly confined, steep channel a distance of approximately 2.8 miles (4.5 kilometers) and drops to the base of Roadhouse Mountain at approximately 689 feet (210 meters) in elevation. From the base of the mountain, the stream meanders through lower gradient tundra for approximately 6.2 miles (10 kilometers), before discharging into Iliamna Lake at the west side of Eagle Bay at an elevation of 35 feet (11 meters). The representative road alignment crosses this watershed at the base of Roadhouse Mountain at elevations ranging from 315 to 522 feet (96 to 159 meters). Within the Eagle Bay T1 watershed, there are six primary and three support survey sites (Table 15.3-1). One of the primary survey sites (F 26.46) is located on Eagle Bay T1, and the other sites are located on tributaries to Eagle Bay T1.

The Eagle Bay Creek watershed consists of two significant streams: the west and east branches of Eagle Bay Creek. West Branch Eagle Bay Creek drains the southeast side of Roadhouse Mountain, originating at approximately 2,558 feet (780 meters) in elevation; it is similar in character to Eagle Bay T1. East Branch Eagle Bay Creek drains a low-lying area to the east of Roadhouse Mountain, originating at less than 399 feet (120 meters) elevation. The representative road alignment intersects this watershed group at one location within each of these streams (primary survey sites MP_29.6 and MP_30.7; Table 15.3-1). These two primary survey sites are south of Roadhouse Mountain at elevations ranging 236 to 276 feet (72 to 84 m; Figure 15.3-2). In addition, there are two support survey sites in the Eagle Bay Creek watershed.

Channel Morphology

Channel morphology data indicated that the stream channels in Roadhouse/Northeast Bay/Eagle Bay Watershed Group were both narrow and shallow, with a mean bankfull width of 7.9 feet (2.46 m; n = 7) and a mean depth of 0.5 feet (0.19 meters; n = 5). Channel slopes were variable, ranging from 0 to 5 percent with a mean gradient of 2.1 percent (Table.15.3-4).

In the Roadhouse Creek watershed, channel morphology data were collected at the one primary survey site (D 24.166) and five support survey sites. The channel at D 24.166 was narrow. Mean bankfull width was 5.6 feet (1.7 meters), and stream gradient was 1 percent (Appendix 15.3A).

In the Eagle Bay T1 watershed, channel morphology data were collected at the six primary survey sites and two support survey sites. The primary survey sites consisted of streams that were slightly wider and higher gradient (2 to 5 percent) than those of the Roadhouse Creek watershed. Bankfull widths ranged from 2 to 11.5 feet (0.6 to 3.5 meters), and wetted widths ranged from 2 to 7.2 feet (0.6 to 2.2 meters; Appendix 15.3A). Channel characteristics at the support survey sites were similar those at the primary survey sites (Appendix 15.1B).

Mean bankfull width for the two Eagle Bay Creek primary survey sites (MP_29.6 and MP_30.7) ranged from 7.5 to 11.5 feet (2.3 to 3.5 meters), and wetted width varied from 6.6 to 7.2 feet (2 to 2.2 meters), while mean water depth ranged from 0.5 to 0.9 feet (0.16 to 0.26 meters; Appendix 15.3A). The gradient was 1 percent in West Branch Eagle Bay Creek (MP_29.6) and close to zero in East Branch Eagle Bay Creek (MP_30.7).

Aquatic Habitat

Habitat composition was measured at nine primary survey sites along the representative road alignment in the Roadhouse/Northeast Bay/Eagle Bay Watershed Group, over a total length of 3,746 feet (1,142 meters; Table 15.3-5). In this watershed group, the predominant habitat types were riffles and scour pools, representing 45.3 and 41.3 percent of the total wetted survey area, respectively. Glides were the next most common habitat type at 11.5 percent, and backwater pools accounted for the remaining 1.8 percent.

Similar to habitat composition, substrate composition was also diverse. All substrate types with the exception of bedrock were observed (Table 15.3-6). Sand/silt, gravel, and cobble ranged from zero to greater than 70 percent among the primary survey sites in this watershed group, with gravel and cobble being the most dominant substrate types among all sites. In the Roadhouse Creek and Eagle Bay T1 watersheds, the substrate was dominated by cobble followed by sand/silt and gravel. In Eagle Bay Creek, the substrate was dominated by gravel, followed by sand/silt-sized particles.

Intermittent flow was noted at several primary and support survey sites within this watershed group. Approximately 26 percent of the total length surveyed for aquatic habitat at the primary survey sites consisted of dry channel (Table 15.3-5). Most of this intermittent flow was observed in the Eagle Bay watershed. Two primary survey sites in the Eagle Bay T1 watershed (MP_27.7 and MP_28.8B) had intermittent surface water or were completely dry during the September 2008 surveys and included 984 feet (300 meters) of dry channel. The primary survey site on Eagle Bay T1.1 (F.25.863) was seasonally inundated; the channel was dry in August 2004, yet flowing in October 2007 after rain events (Appendix 15.3A). One of the support survey sites within the Eagle Bay T1 watershed (F 28.75) was also found to be

seasonally inundated (Appendix 15.3B). In the Roadhouse Creek watershed, support survey site D 24.402 was visited in July 2004 and again in October 2007; it was dry on both occasions, and no additional data were collected (Appendix 15.3B). No seeps, springs, or beaver ponds were observed at any survey sites in the Roadhouse/Northeast Bay/Eagle Bay Watershed Group.

Water Quality

Water quality was measured between August and October at eight primary survey sites in the Roadhouse/Northeast Bay/Eagle Bay Watershed Group (Table 15.3-7), as well as nine support survey sites within these watersheds. Water temperatures at primary survey sites were seasonably cool, with a mean of 43.5°F (6.4°C) and a range from 39°F to 49.6°F (3.9°C to 9.8°C). Field measurements of DO generally indicated good oxygen saturation, with a mean of 10.9 mg/L and a range from 7.0 to 13.0 mg/L. The specific conductivity varied throughout the watersheds, ranging from 34 to 111 µS/cm. The mean pH (7.1) for this watershed group was neutral (Table 15.3-7); however, site-specific pH was variable and ranged from 5.9 to 10.5.

Five primary survey sites had pH measurements that were below the minimum ADEC pH criterion for aquatic life of 6.5. These sites were located in the Roadhouse Creek (D 24.166), Eagle Bay T1 (F 26.46, F 28.49, and F 25.863), and Eagle Bay Creek (MP_29.6) watersheds (Table 15.3-8). Five of these low pH measurements occurred in early October 2007 after rain events, which may potentially alter pH away from its steady-state conditions. For example, the pH in August 2004 at sites F 26.46 and F 28.49 was relatively neutral (approximately 7.2), yet in October 2007, measured pH values were approximately 6.1 (Appendix 15.3A). The pH measurements at three support survey sites sampled in early October 2007 were also below the ADEC minimum pH criterion for aquatic life of 6.5 (Table 15.3-8). One Eagle Bay T1 primary survey site (MP_27.7) exceeded the ADEC maximum pH criterion for aquatic life of 8.5, with a pH field measurement of 10.5 in September 2008. In August 2004, primary survey site F 28.49 had a DO concentration of 6.95, which is below the ADEC minimum DO criterion for aquatic life of 7.0 mg/L.

Fish Resources

Four fish species (two resident salmonids and two resident non-salmonid species) were documented at the primary survey sites in the Roadhouse/ Northeast Bay/Eagle Bay Watershed Group (Figure 15.3-4). Sculpin and Dolly Varden were the predominant fish species, accounting for approximately 42 percent and 34 percent of all fish observed, respectively (Figure 15.3-7). Other species present were rainbow trout (19 percent) and ninespine stickleback (7 percent).

Fish counts were low at the primary survey sites, with a total of 65 fish observed at four sites (D 24.166, F 26.46, F 28.49, and MP_30.7). Primary survey site MP_30.7 on Eagle Bay Creek had the greatest species diversity, with three species (rainbow trout, sculpin and ninespine stickleback) observed there. The other primary survey sites had either sculpin or Dolly Varden present. No fish were observed during survey efforts at four of the primary survey sites: three in Eagle Bay T1 (MP_29.6, MP_27.7, and F 26.863) and one in Eagle Bay Creek (MP_29.6). Fish assemblages at the support survey sites were generally similar to those at the primary survey sites with the exception of rainbow trout; five of the eight support sites that were surveyed for fish supported sculpin, Dolly Varden, and/or ninespine stickleback (Appendix 15.3B).

Although no anadromous fish were documented during fish sampling efforts in the Roadhouse/Northeast Bay/Eagle Bay Watershed Group, coho salmon, sockeye salmon, and Arctic char are known to occur in this watershed group (ADF&G, 2010). Both Eagle Bay T1 and Eagle Bay Creek support Arctic char and spawning sockeye salmon within the transportation corridor study area (ADF&G, 2010). The Anadromous Waters Catalog indicates that Roadhouse Creek supports spawning coho and sockeye salmon below River Mile 6.2 (River Kilometer 10), which is more than 3.1 miles (5 kilometers) downstream from the Roadhouse Creek primary survey site. In addition, this primary survey site is located at, or slightly above, the headwaters of this watershed where the habitat is not conducive to supporting larger anadromous salmonids. Thus, it is unlikely that anadromous species occur along the representative road alignment within the Roadhouse Creek watershed.

15.3.6.5 Youngs/Chekok/Canyon Watershed Group

This watershed group includes three watersheds that drain into the northern edge of Iliamna Lake from Chekok Bay to Fox Bay (Figure 15.3-2): Youngs Creek (MP 33.1 to MP 34.6), Chekok Creek (MP 37.7 to MP 38.3), and Canyon Creek (MP 38.7). The representative road alignment crosses within the lower reaches of streams in this watershed group near Iliamna Lake. There are three primary survey sites in this watershed group that were sampled between 2004 and 2008 (Table 15.3-1). Two were located on Chekok Creek (F 39.65 and F 39.59), and one was located on Canyon Creek (F 40.2). There are no support survey sites in this watershed group.

The Youngs Creek watershed includes two major tributaries: a west branch and an each branch. The west branch drains the east side of Roadhouse Mountain for a distance of approximately 8.7 miles (14 kilometers) before joining the east branch, which drains the south side of an unnamed mountain and low-lying areas to the east-northeast for a distance of approximately 10 miles (16 kilometers). Downstream of where these two branches merge, Youngs Creek flows for approximately 3.1 miles (5 kilometers) before discharging into Iliamna Lake at Chekok Bay.

Chekok Creek originates at Chekok Lake, which lies in a valley between unnamed mountains, and flows nearly 18.6 miles (30 kilometers) in a south-southwest direction before discharging into Iliamna Lake. Chekok Creek has a wide and very dynamic channel that frequently shifts in the active floodplain. Chekok Creek T1, one of the significant tributaries within the watershed, is located in the lower portion of the watershed. It originates at approximately 315 feet (96 meters) in elevation and drains low-lying areas to the west of Chekok Creek for nearly 5.6 miles (9 kilometers) before entering Chekok Creek at approximately River Mile 0.1 (River Kilometer 0.2).

Canyon Creek drains the northern side of Knutson Mountain from its headwaters at approximately 3,000 feet (914 meters). From there, it flows through a deep canyon for approximately 10.6 miles (17 kilometers) and into a wide forested valley, where it meanders approximately 6.2 miles (10 kilometers) before discharging into Iliamna Lake at Fox Bay at an elevation of 35 feet (11 meters). The canyon reach of the creek is high gradient and contains several waterfalls of various sizes, which create migration barriers for anadromous fish. The representative road alignment would cross Canyon Creek downstream of the canyon reach, where the stream channel is wide and very dynamic within the floodplain portion of the wide forested valley. The floodplains of Canyon and Chekok creeks overlap in the lower portions of their valleys, and periodically, their channels converge before discharging into Fox Bay.

Within the Youngs/Chekok/Canyon Watershed Group, several of the headwater tributaries originate in the mountains and are steep, highly confined channels flowing from 1,968 feet (600 meters) to the base of the mountains at approximately 984 feet (300 meters). The channel forms transition from highly confined channels to low-gradient meandering channels at elevations below approximately 689 feet (210 meters). The riparian corridor of Youngs Creek is composed of tundra, while the lower valleys of Chekok and Canyon Creek watersheds are composed of forested habitat. The representative road alignment traverses lower gradient, perennial streams in the lower portion of these three watersheds at an elevation of 157.4 feet (48-m; Map 15.3-2).

Fish and aquatic habitat surveys were conducted at three primary survey sites in Chekok and Canyon creeks. Given the dynamic nature of these creeks in the vicinity of the representative road alignment and that anadromous fish presence has been previously documented in these stream reaches (ADF&G, 2010), these three upstream survey sites were designated as representative primary survey sites even though they are located 0.9 miles (1.4 kilometers) to 1.4 miles (2.2 kilometers) upstream from the representative road alignment. There were no support survey sites in the Chekok Creek and Canyon Creek watersheds.

Channel Morphology

The channel morphology data for the Youngs/Chekok/Canyon Watershed Group were highly variable (Table 15.3-4; Appendix 15.3A). Chekok Creek was surveyed at two primary survey sites, one representing the main channel (F 39.65) and the other a side channel (F 39.59). The Chekok Creek side channel primary survey site was relatively narrow, with an 18-foot (5.5-meter) bed width and a moderate slope (1.5 percent). The stream gradient was similar at the main channel Chekok Creek primary survey site. However, the channel was nearly three times wider, as indicated by a mean bed with of 69 feet (21 meters). The Canyon Creek primary survey site (F 40.2) was both steeper and wider, with a gradient of 3 percent and a mean bed width of 80 feet (24.4 meters).

Aquatic Habitat

Habitat composition for the Youngs/Chekok/Canyon Watershed Group is summarized in Table 15.3-5. A total of 2,624 feet (800 meters) of stream was surveyed for habitat in this watershed group. Overall, the surveyed habitat was dominated by riffles (88 percent), with a lesser amount of scour pool habitat (12 percent).

The substrate was dominated by cobbles at the main channel Chekok and Canyon Creek primary survey sites (F 39.65 and F 40.2) and by gravels at the Chekok side channel primary survey site (F 39.59). Wood pieces and overhanging vegetation were present at the sites, and beaver activity was not evident at any of the sites surveyed.

Water Quality

Water quality was measured at the three primary survey sites in August 2004. The water temperature was warm (over 55.4°F [13°C]) at the two wider, main channel primary survey sites (F 39.65 and F 40.2) and resulted in the highest mean water temperature of all watershed groups (Table 15.3-7). Sockeye salmon adults and juveniles were present at the locations, and the field temperature measurement at primary survey site F 40.2 of 55.6°F (13.1°C) exceeded the ADEC maximum temperature criterion for spawning and egg and fry incubation areas (Table 15.3-8). A 61.7°F (16.5°C) field measurement at survey site F

39.65 exceeded the ADEC maximum temperature criteria for spawning, egg and fry incubation, and for rearing areas and migration routes (Table 15.3-8).

The mean pH at the three primary survey sites was 6.7, and DO concentrations at all three primary survey sites were within the acceptable range of values for the ADEC DO criteria for aquatic life (i.e., between 7.0 and 17.0 mg/L in fish bearing waterbodies; Table 15.3-7). Similar to other watershed groups, the specific conductivity was low, ranging from 19 to 49 µS/cm. One pH measurement (6.14), collected at the Chekok Creek primary survey site F 39.59, was below the minimum pH criterion (Table 15.3-8). No other water quality data were outside the ADEC range of criterion for this watershed group.

Fish Resources

Four fish species (one anadromous salmonid, two resident salmonids, and one resident non-salmonid species) were documented at the primary survey sites in the Youngs/Canyon/Chekok Watershed Group (Table 15.3-9; Figure 15.3-4). Sockeye salmon (96.3 percent) were the predominant species observed (Figure 15.3-8). The three other species present were rainbow trout, Dolly Varden, and sculpin at 1.7, 0.1, and 1.9 percent, respectively.

Overall fish counts were highest in this watershed group due to thousands of sockeye salmon adults observed at primary survey sites F 39.65 and F 40.2. These primary survey sites each had three species observed. At the other primary survey site, the side channel on Chekok Creek (F 39.59), only sculpin were present. Although not evident from our sampling, the Anadromous Waters Catalog indicates that spawning sockeye salmon, coho salmon, and Arctic char are present in all three watersheds within this watershed group (ADF&G, 2010).

15.3.6.6Knutson Bay/Pedro Bay Watershed Group

The Knutson Bay/Pedro Bay Watershed Group consists of the Knutson Creek watershed, and 10 small unnamed tributary watersheds that drain the western and southern sides of Knutson Mountain and discharge into Knutson Bay. There is also one unnamed tributary watershed that discharges into Pedro Bay (Figure 15.3-2). The representative road alignment intersects streams within this watershed group from MP 39.8 to MP 51.7 at elevations ranging from approximately 138 to 512 feet (42 to 156 meters). Eighteen primary survey sites within the Knutson Bay/Pedro Bay Watershed Group were surveyed in August 2004 (Table 15.3-1; Figure 15.3-2). Sixteen of these primary survey sites are located in the unnamed watersheds of Knutson Bay. The other two primary survey sites were located on Knutson Creek (F 49.5) and the tributary to Pedro Bay (F 51.85). There are no support survey sites in this watershed group.

Within this watershed group, Knutson Creek is the dominant watershed with respect to drainage area (Figure 15.3-2). The highest elevation in the Knutson Creek drainage is Knutson Mountain at an elevation of approximately 4,133 feet (1,260 meters). The lowest elevation is 46 feet (14 meters) and occurs at the stream outlet to Iliamna Lake. The watershed is bounded by Knutson Mountain to the west and unnamed mountains to the north and east. Knutson Creek originates at an elevation of approximately 2,952 feet (900 meters) and flows southwest through an approximately 8.7-mile (14-kilometer) long, confined valley. The valley then widens, and the creek meanders for approximately 1.9 miles (3 kilometers) before emptying into the eastern end of Knutson Bay.

The remainder of this watershed group consists of the unnamed Knutson and Pedro Bay tributaries. Knutson Bay T1 originates from the southwest side of Knutson Mountain and is the largest of the 10 unnamed tributaries to Knutson Bay. The other nine unnamed tributaries drain the southern side of Knutson Mountain. These streams are relatively small, steep channels flowing through forested habitat; they appear to be seasonally inundated by surface runoff from rain events or snow melt from Knutson Mountain. Pedro Bay T1 originates from an unnamed mountain at an elevation of approximately 1,771 feet (540 meters) and flows about 2.9 miles (4.6 kilometers) west and south discharging into Iliamna Lake near the community of Pedro Bay.

All of the primary survey sites in this watershed group that were surveyed in 2004 consisted of dry channels, except for primary survey site F 49.5 on Knutson Creek (Appendix 15.3A). Channel morphology, aquatic habitat, water quality, and fish presence data were collected at F 49.5, and limited channel morphology and substrate data were collected at one of the dry primary survey sites (F 51.85; MP 50.4) in the Pedro Bay watershed.

Channel Morphology

Channel characteristics largely differed between the Knutson Creek and Pedro Bay T1 primary survey sites (Appendix 15.3A). At the Knutson Creek primary survey site (F 49.5), measured bed width was 168 feet (51.2 meters), whereas bed width at the Pedro Bay T1 primary survey site (F 51.85) was only 9.2 feet (2.8 meters), with a mean bed width for the two sites of 88.5 feet (26.99 meters; Table 15.3-4). Mean channel gradient for these two sites was 4.5 percent. The channel at the Knutson Creek primary survey site had a more moderate gradient (3 percent) than the channel at the Pedro Bay T1 primary survey site (6 percent).

Aquatic Habitat

In the Knutson Bay/Pedro Bay Watershed Group, approximately 1,312 feet (400 meters) of stream were surveyed for aquatic habitat data at the Knutson Creek site F 49.5 (Table 15.3-5). The dominant aquatic habitat type was riffle (75 percent), with scour pools comprising the remainder of the survey area.

Overall, gravel and cobble were the predominant substrate types at the Knutson Creek and Pedro Bay T1 sites (F 49.5 and F 51.85, respectively; Table 15.3-6). Bed material at the Knutson Creek site was predominantly cobble and boulder, with finer substrates (gravel and sand/silt) also present. Gravel (60 percent) dominated the dry channel at the Pedro Bay T1 site, and cobble and sand (20 percent each) comprised the remainder of the surveyed channel area. Overhanging vegetation and large woody debris were present in less than 10 percent of the survey area at both sites. No beaver activity was observed at either site.

Water Quality

Water quality parameters were measured in August 2004 at the Knutson Creek primary survey site F 49.5. Knutson Creek appears to be among the warmer (51.3°F [10.7°C]) primary survey sites documented during the transportation corridor study (Table 15.3-7). The pH (6.5), DO (12.2 mg/L), and specific conductivity (21 µS/cm) measurements were similar to those recorded at other primary survey sites in other watershed groups. The Knutson Creek water quality measurements met the ADEC water quality standards for aquatic life (Table 15.3-2).

Fish Resources

During the Knutson Creek fish survey at F 49.5, sockeye salmon, Dolly Varden, and sculpin were documented (Table 15.3-9). Within the 1,312-foot (400-meter) sample length, 89 adult sockeye salmon (accounting for 81.7 percent of the total fish observations; Figure 15.3-9) were observed spawning and building redds in riffle habitat with mixed substrate sizes. Dolly Varden and sculpin accounted for the remainder of the observations (11 and 7.3 percent, respectively; Figure 15.3-9). The Anadromous Waters Catalog also indicates the presence of Arctic char in Knutson Creek (ADF&G, 2010).

Within the Knutson Bay/Pedro Bay Watershed Group, there are two other watersheds intersected by the representative road alignment that are known to support anadromous fish in their lower reaches (ADF&G, 2010). Knutson Bay T1 supports spawning sockeye salmon and Arctic char presence in the lower mile (1.7 kilometers) of river. While the Pedro Bay T1 primary survey site (F 51.85) was dry at the time of sampling, spawning sockeye salmon have been documented approximately 1,640 feet (500 meters) downstream of this site, and their spawning distribution extends from this location downstream to Iliamna Lake (ADF&G, 2010). The presence of a waterfall downstream may preclude anadromous fish access to site F 51.85.

15.3.6.7Pile Bay/Lonesome Bay Watershed Group

The Pile Bay/Lonesome Bay Watershed Group consists of the Pile River, which discharges into Pile Bay, and two unnamed tributary watersheds that discharge into Lonesome Bay (Figure 15.3-2). The representative road alignment intersects streams within this watershed group from MP 54.3 to MP 59.5 at elevations ranging from less than 80 feet (24 meters) at site F 61.26 on the Pile River to 640 feet (195 meters) at site F 55.75 on the unnamed Lonesome Bay T1 tributary.

The Pile River is the dominant watershed within this group with respect to drainage area (Figure 15.3-2). The Pile River, originating from glaciers in the Lake Clark Wilderness Area, flows southwest through a valley bounded by Three Sisters Mountain to the east and unnamed mountains to the west, for a distance of approximately 47 kilometers before discharging into Iliamna Lake at Pile Bay.

Three primary survey sites within this watershed group were surveyed in August 2004 (Table 15.3-1; Figure 15.3-2). Dry channels were observed at both F 55.75 and F 56.761; therefore, no channel morphology, aquatic habitat, water quality, and fish species data were collected at the primary survey sites in the Lonesome Bay T1 and Lonesome Bay T2 tributaries (Appendix 15.3A). These two Lonesome Bay tributaries have not been mapped by ADF&G as anadromous fish streams (ADF&G, 2010). The dry conditions observed in August 2004 indicate that these streams are seasonally ephemeral at least in dry years and, as such, are unlikely to provide the spawning and rearing habitat that is more commonly found in perennial streams. Channel morphology, aquatic habitat, water quality, and fish presence data were collected at the Pile River primary survey site F 61.26. There are no support survey sites in this watershed group.

Channel Morphology

At the Pile River primary survey site F 61.26, measured bed width was 211 feet (64.2 meters), and wetted width was 233 feet (71 meters; Table 15.3-4). Channel gradient was moderate (2 percent).

Aquatic Habitat

Aquatic habitat data were collected at the Pile River site F 61.26 over a length of 656 feet (200 meters; Table 15.3-5). The aquatic habitat within the area surveyed was composed entirely of glide habitat.

Bed material at the Pile River primary survey site was predominantly cobble (60 percent), and finer substrates (sand/silt) comprised the remainder of the surveyed channel area. Overhanging vegetation and large woody debris were present in less than 10 percent of the survey area. No beaver activity was observed.

Water Quality

Water quality parameters were measured in August 2004 at the Pile River primary survey site F 61.26. The Pile River primary survey site is among the warmer (50.2 °F [10.1 °C]) primary survey sites documented during the transportation corridor study (Table 15.3-7). The pH (6.52), DO (12.05 mg/L), and specific conductivity (22.1 µS/cm) measurements were similar to those recorded at other primary survey sites in other watershed groups. The Pile River water quality measurements met the ADEC water quality standards for aquatic life (Table 15.3-2).

Fish Resources

During the Pile River fish survey at F 61.26, sculpin and threespine stickleback were documented (Table 15.3-9). Due to the large size of the Pile River, portions of the 656-foot (200-meter) long survey area were surveyed for fish along the stream margins; five threespine stickleback and one sculpin were observed (83.3 and 16.7 percent, respectively; Figure 15.3-10). While no salmon were observed during fish surveys, the Anadromous Waters Catalog indicates the presence of spawning sockeye salmon and Arctic char in the Pile River (ADF&G, 2010).

15.3.6.8Iliamna River Watershed Group

The Iliamna River Watershed Group contains six primary and nine support survey sites that were visited during the 2004 through 2008 study period (Table 15.3-1; Figure 15.3-1). The Iliamna River originates on the west side of the Chigmit Mountains and flows southwest for approximately 31 miles (50 kilometers) before emptying into Iliamna Lake. The watershed is bounded by Three Sisters Mountain to the west and unnamed mountains to the north and east. The representative road alignment from MP 64.9 to MP 71.9 crosses the lower end of the Iliamna River watershed at elevations that range from 118 to 374 feet (36 to 144 meters).

One primary survey site (J 68.0; MP 65.4) is located on the mainstem Iliamna River (Figure 15.3-2). The other five primary survey sites are distributed among three subwatersheds, including two unnamed Iliamna River tributaries (I 65.47 and J 67.75; MP 64.9 and MP 65.2, respectively) and Chinkelyes Creek (K 70.14, MP_70.3, and MP_71.9; MP 68.8, MP 70.3, and MP 71.9, respectively). Chinkelyes Creek originates in the Chigmit Mountains and flows for approximately 14.3 miles (23 kilometers) before emptying into the lower reach of Iliamna River. Chinkelyes Creek drains a much larger watershed compared to the other unnamed Iliamna River tributaries. One of the Chinkelyes Creek primary survey sites (MP_71.9) was located on the mainstem, and the other two were located on tributaries. Each of these

six primary survey sites was surveyed in either August 2004 or September 2008. One of these primary survey sites (I 65.47; MP 64.9) was dry when visited in August 2004 (Appendix 15.3A).

Channel Morphology

Within the Iliamna River Watershed Group, the channel characteristics varied between the mainstem and tributary crossing sites. The channels at the Iliamna River and Chinkelyes Creek mainstem crossings were relatively wide and large, compared to the narrower channels present at tributary sites. Channel size was best indicated by bed width for this watershed group. Mean bed width within this watershed group was 64 feet (19.53 meters; Table 15.3-4). Site-specific bed widths ranged from 19.7 feet (6 meters) at primary survey site J 67.75 (MP 65.2) to 170 feet (51.8 meters) at the mainstem Iliamna River primary survey site, J 68.0 (MP 65.4). Channel characteristics at the support survey sites within this watershed group were highly consistent with those observed for the primary survey sites; the mainstem Iliamna River and Chinkelyes Creek were characterized by wide channels, while tributary channels were narrow (Appendix 15.3B).

Channel gradients were more moderate at the Iliamna River sites than at the Chinkelyes Creek sites. Channel slope ranged from 1 to 1.5 percent in the Iliamna River as compared to 3 to 4 percent in Chinkelyes Creek (Appendix 15.3A). The mean channel slope for the primary survey sites within the Iliamna River Watershed Group was 2.7 percent (Table 15.3-4). The support survey sites within this watershed group had a similar gradient ranging from 0.1 to 2.5 percent (Appendix 15.3B).

Water depth was measured at channel morphology transect locations for primary survey sites MP_71.9 and MP_70.3, located on Chinkelyes Creek and Chinkelyes T1, respectively. Mean water depth was 1.3 feet (0.4 meters; Table 15.3-4). The Chinkelyes Creek primary survey site was slightly deeper at 1.6 feet (0.5 meters) than the tributary primary survey site, which had a depth of 1 foot (0.3 meters).

Aquatic Habitat

A total length of 3,588 feet (1,094 meters) of stream habitat was surveyed at four of the primary survey sites in the Iliamna River Watershed Group (J 68.0, K 70.14, MP_70.3, and MP_71.9). The habitat was predominantly fast-water habitat, with approximately 63 percent glide, 26 percent riffle, and 3 percent cascade documented (Table 15.3-5). The mainstem Iliamna River primary survey site (J 68.0) consisted entirely of glide habitat, which accounts for a large percentage of the total wetted surface area for this watershed group. Scour pools (21.9 percent) at primary survey site K 70.14 (MP 68.8) and a single backwater pool at primary survey site MP_71.9 (0.2 percent) accounted for the remainder of the aquatic habitat surveyed. Habitat composition was not recorded at two of the primary survey sites (I 65.47 and J 67.75) due to dry channel conditions.

Within this watershed group, the dominant and subdominant substrates were sand/silt and cobble, respectively (Table 15.3-6), although substrate composition was distinct between the Iliamna River watershed and the Chinkelyes Creek watershed primary survey sites. Sand/silt was the dominant substrate type within the Iliamna River watershed, accounting for 95 percent of the substrate composition at primary survey sites J 67.75 and J 68.0; a small percentage of gravel and boulder was also present (Appendix 15.3A). At the Chinkelyes Creek mainstem and tributary crossing primary survey sites, cobble (20-50 percent) and boulder (19-60 percent) tended to predominate; gravel (10-24 percent) and sand/silt (7-10 percent) accounted for the remainder of the substrate composition. The prevalence of larger

substrates was consistent with the high gradient and high energy nature of the Chinkelyes Creek watershed.

Support survey sites in this watershed group had habitat similar to primary survey sites, including differences between subwatersheds. However, one notable difference was observed. One Iliamna River support survey site (I 65.71) had a different habitat that was comprised of 60 percent riffle and 40 percent scour pool, with an entirely cobble and gravel substrate (Appendix 15.3B).

Two Iliamna River primary survey sites did not have flowing water at the time of the surveys. Primary survey site I 65.47 was completely dry, whereas some ponded water was present at primary survey site J 67.75. Both of these primary survey sites were located on an unnamed tributary to the Iliamna River.

Large woody debris was relatively sparse throughout the Iliamna River Watershed Group due to a lack of source trees from the riparian zone. Overhanging vegetation was relatively sparse at the Iliamna River watershed primary survey sites and altogether absent at the Chinkelyes Creek primary survey sites (Appendix 15.3A). No beaver ponds, seeps, or springs were documented at primary survey sites in the Iliamna River and Chinkelyes Creek watersheds. Culverts were present at primary survey sites J 67.75 and MP_70.3.

Water Quality

Overall, water quality conditions in the Iliamna River Watershed Group were suitable for a variety of fishes (Table 15.3-7). Water temperatures appeared to be seasonably appropriate, with warmer (approximately 54 to 55ºF [12 to13ºC]) and cooler (approximately 44 to 46 ºF [6.5 to 7.5 ºC]) temperatures observed in August 2004 and September 2008, respectively (Appendix 15.3A). The pH was generally neutral (mean = 7.8), and DO was saturated at most sites (mean = 9.6 mg/L). Specific conductivity was low and uniform, ranging from 11 to 43 µS/cm.

In a few instances, the ADEC water quality standards for aquatic life were not met for DO and pH (Table 15.3-8). DO was below the ADEC minimum DO criterion for aquatic life at one primary survey site (J 67.75; MP 65.2), which had a DO concentration of 4.51 mg/L. The sample reach for this site, however, contained shallow and turbid ponded water at the downstream end of a culvert (see photo in Appendix 15.3A). DO within this water source would be expected to be low. DO concentrations at the other primary survey sites met ADEC DO criteria for aquatic life and ranged from 7.82 to 12.1 mg/L. These values were similar to concentrations observed elsewhere in the transportation corridor study area (Table 15.3-7). Two primary survey sites (J 68.0 and MP_70.3) did not meet the ADEC water quality criterion for aquatic life for pH, with pH measurements of 6.4 and 11.0, respectively.

Among the support survey sites within the Iliamna River Watershed Group, there were three instances where the measured pH did not meet the ADEC minimum pH criterion for aquatic life (Table 15.3-8). Field measurements for pH at survey sites I 65.07, I 65.71, and K 73.07 ranged from 5.8 to 6.35. A water temperature of 57ºF (14°C) was observed at survey site I 65.63; it is unclear if this temperature meets the ADEC water temperature criteria for aquatic life, since it is currently unknown if habitat at this site is used for spawning and egg incubation.

Fish Resources

Three fish species (one anadromous salmonid, one resident salmonid, and one resident non-salmonid species) were documented at the primary survey sites in the Iliamna River Watershed Group (Table 15.3-9). Most notably, an estimated count of "thousands" of adult sockeye were observed migrating past the mainstem Iliamna River primary survey site (J 68.0), which accounted for 97.8 percent of the fish observed in this watershed group (Figure 15.3-11). Twenty-one Dolly Varden and one sculpin (approximately 2.1 and 0.1 percent of the species composition, respectively) were observed in one of the Chinkelyes Creek tributary primary survey sites (K 70.14; Figure 15.3-4). No fish were observed at the other primary survey sites.

Fish presence was similar for support survey sites within this watershed group. Sockeye salmon, Dolly Varden, and sculpin were observed among the four Iliamna River support survey sites, and only Dolly Varden and sculpin were present at the support survey sites in Chinkelyes Creek (Appendix 15.3B; Figure 15.3-4). Approximately 3,000 adult sockeye salmon were observed migrating, redd building, and actively spawning at support survey sites I 65.07 and I 65.11 in August 2004 (Appendix 15.3B). Although no anadromous fish were observed during fish sampling efforts in Chinkelyes Creek, sockeye salmon have been documented in Chinkelyes Creek (ADF&G, 2010).

15.3.7 Summary

The Pebble Project transportation corridor Bristol Bay drainages study area (MP 0 to approximately MP 73) traverses multiple rivers, streams, and channels that eventually drain into Iliamna Lake. To characterize these waterways, 55 primary survey sites (located directly on or near the representative road alignment) and 42 support survey sites (located upstream and/or downstream of the primary survey sites or on nearby tributaries) were established. Each site was designated to one of eight watershed groups: Upper Talarik (UT), Newhalen, Isolated Watersheds, Roadhouse/Northeast Bay/Eagle Bay, Youngs/Chekok/Canyon, Knutson Bay/Pedro Bay, Pile Bay/Lonesome Bay, and Iliamna River.

During transportation corridor fish and aquatic habitat surveys along the representative road alignment, there were a variety of stream channels encountered ranging from small shallow channels of headwater reaches and tributaries to the wider and deeper mainstem channels of Canyon Creek, Knutson Creek, Iliamna River, and Pile River. Channel bed widths ranged from approximately 2 to 211 feet (0.6 to 64.2 meters). Stream gradients varied from nearly 0 to 6 percent and tended to be steepest in tributaries to Eagle Bay, Chinkelyes Creek, and Pedro Bay.

Approximately half of the primary survey sites were dry or had intermittent flow at the time of initial sampling. A second visit to dry channels showed that a few of these primary survey sites had flowing water after the fall rains had commenced. Forty-two percent of the primary survey sites were without flowing water in the channel for all observations. All but two of these dry sites were located between Roadhouse Mountain and the Iliamna River, with the majority of them located in Knutson Bay tributaries.

Where the channels contained flowing water, the primary survey sites predominantly consisted of fast-water riffle and/or glide habitats (greater than 85 percent of the total wetted area surveyed) with cobble and gravel as the most prevalent substrates. Pools were present in lesser

amounts accounting for approximately 13 percent of the habitat surveyed. Cascade habitat was encountered only at one Chinkelyes Creek primary survey site.

Water quality was generally good at all sites with seasonally appropriate temperatures and saturated DO. High temperature measurements exceeding the ADEC maximum water temperature criteria for salmon were noted at two primary survey sites. These measurements were taken in early August 2004. The pH overall was neutral, but there were many field measurement that did not meet the ADEC pH criteria for aquatic life. Measurements at nine sites indicated that the pH exceeded these criteria. These sites were located in Upper Talarik Creek and its tributaries (4 exceedences), Newhalen River tributaries (3 exceedences), a tributary to Eagle Bay (1 exceedence), and a tributary to Chinkelyes Creek (1 exceedence). Additionally, there were eight primary survey sites, located in four watershed groups, where the field measurement of pH was too low. Five of these eight field measurements were taken in early October 2007 following rain events, which may potentially alter pH away from its steady-state conditions. Specific conductivity is not included among the ADEC water quality criteria for aquatic life; however specific conductivity was considered to be consistently low across all primary survey sites.

Collectively, ten fish species were documented during the fish surveys conducted at the primary survey sites. Dolly Varden and sculpin were the most common species and found at primary and support survey sites within seven of the eight watershed groups that were surveyed for fish. Rainbow trout were observed in small numbers at four primary survey sites: two sites in the Upper Talarik Creek watershed, one in the Eagle Bay Creek watershed, and one in Chekok Creek. Chinook salmon were documented only in Upper Talarik Creek primary survey sites but are known to be present within the Newhalen River based on ADF&G's Anadromous Waters Catalog (ADF&G, 2010). Coho salmon were found at primary survey sites within the Upper Talarik Creek and Newhalen watershed groups. The Anadromous Waters Catalog indicates coho salmon also have a presence in Youngs, Chekok, and Canyon creeks. Adult sockeye salmon were documented at primary survey sites in Chekok, Canyon, and Knutson Creeks, and the Iliamna River, and at support survey sites in the Iliamna River and a tributary to the Newhalen River. Although not evident during these surveys, sockeye salmon have been observed spawning in Upper Talarik Creek in the vicinity of the downstream-most primary survey sites (Chapter 15, Appendix 15.1B) and in the Pile River and tributaries to the Knutson and Pedro bays (ADF&G, 2010). No fish were observed at primary and support survey sites in the Isolated Watershed Group. This was not surprising as no anadromous fish habitat has been documented in the Isolated Watershed Group.

15.3.9 Glossary

Adfluvial. A migratory population of freshwater fish that move from lake environments where they rear and mature into flowing streams and rivers where they spawn and develop early life history stages.

Anadromous. Fish species that reside in marine waters but migrate into freshwater for spawning and rearing of early life history stages.

Bankfull width. A measure of the width of the wetted channel at the height of bankfull discharge. It is measured as the horizontal distance, perpendicular to the deepest part of the channel, between corresponding bankfull height locations on opposite channel banks.

Bed width. Channel bed width is independent of the current water level, and equates to the distance between the bottom-of-the-left-bank and bottom-of-the-right-bank.

Baseline. For this report; baseline represents the pre-development watershed situation, including physical, chemical and biological conditions, between 2004 and 2008.

Channel morphology. The form or shape of a stream channel, including the contours of its bed.

Ephemeral stream. Streams with temporary surface water flow.

Exceedence. The occurrence of a measured value that is greater than the maximum expected value or criterion for a given parameter.

Gradient. Channel gradient is the change in water surface elevation between end points of a channel segment.

Intermittent Stream. Stream with periodic surface water flows.

Mean. The average value.

Non-salmonid fishes. Fishes belonging to any family other than Salmonidae.

Radio telemetry. The use of various types of radio-transmitters (VHF, satellite, or GPS) attached to species to track their movements.

Resident fishes. Fish that reside their entire life cycle in the local freshwater stream/lake, network.

Salmonid. Fishes belonging to the Family Salmonidae.

Seep. A wet place where a liquid, usually groundwater, oozes from the ground to the surface. Seeps are usually not flowing but may enter or form flowing streams.

Spring. Any natural occurrence where water flows to the surface of the earth from below the surface. Thus, a spring is where the aquifer surface meets the ground surface. Springs usually have a flow rate associated with their surface water discharge.

Substrate. Materials that make up the stream bed, categories include organic material, silt, sand, gravels, cobbles, boulders, and bedrock.

Notes:

a. T = tributary. This notation is used to denote unnamed tributaries to a specified stream (e.g., Knutson Bay T1 is an unnamed tributary to Knutson Bay, and Knutson Bay T1.1 and T1.2 are two different tributaries to Knutson Bay T1).

b. Milepost (MP), in miles, represents the distance along the representative road alignment between the representative road alignment's western terminus at the edge of the Pebble Deposit and the primary survey site location.

c. Support survey sites are located on the same stream as the primary survey site or on a nearby tributary.

TABLE 15.3-2
Alaska Department of Environmental Conservation Water Quality Standards for Growth and Propagation of Fish, Shellfish, Other Aquatic Life, and Wildlife in Freshwater

Water Quality Parameter	Water Quality Standard
Water Temperature	May not exceed 20°C at any time. The following maximum temperatures may not be exceeded, where applicable: • Migration routes 15°C • Spawning areas 13°C • Rearing areas 15°C • Egg & fry incubation 13°C • For all other waters, the weekly average temperature may not exceed site-specific requirements needed to preserve normal species diversity or to prevent appearance of nuisance organisms.
Dissolved Oxygen	DO must be greater than 7 mg/L in waters used by anadromous or resident fish. In no case may DO be less than 5 mg/L to a depth of 20 centimeters in the interstitial waters of gravel used by anadromous or resident fish for spawning. For waters not used by anadromous or resident fish, DO must be greater than or equal to 5 mg/L. In no case may DO be greater than 17 mg/L. The concentration of total dissolved gas may not exceed 110 percent of saturation at any point of sample collection.
pH	May not be less than 6.5 or greater than 8.5. May not vary more than 0.5 pH unit from natural conditions.

Source: ADEC, 2009.

°C = degrees Celsius.

DO = dissolved oxygen.

mg/L = milligrams per liter.

TABLE 15.3-3
Locations of Upper Talarik Creek Watershed Representative Road Alignment Primary Survey Sites

MP_05.4		UT 1.360
MP_05.6	45.0	
MP_06.4		UT 1.340

Notes:

a. Primary survey sites in the Upper Talarik Creek Watershed are located on the mainstem Upper Talarik Creek (as indicated by the river kilometer) or on a tributary to Upper Talarik Creek (as indicated by the tributary name). River kilometer, in kilometers, represents the distance along the course of the river between the site location and the mouth of the river.

Pile Bay / Lonesome Bay	1	10.1	—	0	12.05	—	0	6.52	—	0	22.1	—
Iliamna River	5	10.2 (6.5-12.9)	1.34	0	9.6 (4.5-12.1)	1.49	1	7.8 (6.4-11.0)	0.85	2	20 (11-43)	5.9

Notes:

a. Water temperature may not exceed 20 ^{o}C at any time, 15 ^{o}C within migration routes and rearing areas, or 13 ^{o}C in spawning, egg, and fry incubation areas (ADEC water quality standards for the growth and propagation of fish, aquatic life, and wildlife; ADEC, 2009).

b. Dissolved oxygen must be greater than 7 mg/L in fish bearing waterbodies; may not be less than 5 mg/L in non-fish bearing waterbodies; may not be greater than 17 mg/L in any waterbody (ADEC water quality standards for the growth and propagation of fish, aquatic life, and wildlife; ADEC, 2009).

c. pH may not be less than 6.5 or greater than 8.5 in any freshwater waterbody (ADEC water quality standards for the growth and propagation of fish, aquatic life, and wildlife; ADEC, 2009).

— = no data available or standard error not calculated when the sample size is less than 3.

µS/cm = microSiemens per centimeter

		Chinkelyes T1	MP_70.3	9/15/08			11

Notes:

a. Support survey sites for the representative road alignment.

b. Water temperature may not exceed 20 ^{o}C at any time, 15 ^{o}C within migration routes and rearing areas, or 13 ^{o}C in spawning, egg, and fry incubation areas (ADEC water quality standards for the growth and propagation of fish, aquatic life, and wildlife; ADEC, 2009).

c. Dissolved oxygen must be greater than 7 mg/L in fish bearing waterbodies; may not be less than 5 mg/L in non-fish bearing waterbodies; may not be greater than 17 mg/L in any waterbody (ADEC water quality standards for the growth and propagation of fish, aquatic life, and wildlife; ADEC, 2009).

d. pH may not be less than 6.5 or greater than 8.5 in any freshwater waterbody (ADEC water quality standards for the growth and propagation of fish, aquatic life, and wildlife; ADEC, 2009).

Blanks indicate that the measured value met the Alaska Department of Environmental Conservation Water Quality Standards.

TABLE 15.3-9
Fish Species Observed at Representative Road Alignment Primary and Support Survey Sites, Transportation Corridor, Bristol Bay Drainages Study Area

		Watershed Group [a,]						
Common Name	**Scientific Name**	**Upper Talarik**	**Newhalen**	**Roadhouse/ Northeast Bay/Eagle Bay**	**Youngs/ Canyon/ Chekok**	**Knutson Bay/Pedro Bay**	**Pile Bay/ Lonesome Bay**	**Iliamna River**
Chinook salmon	*Oncorhynchus tshawytscha*	**X**						
Coho salmon	*Oncorhynchus kisutch*	**X**	**X**					
Sockeye salmon	*Oncorhynchus nerka*		x		**X**	**X**		**X**
Arctic grayling	*Thymallus arcticus*	**X**	**X**					
Dolly Varden	*Salvelinus malma*	**X**	x	**X**	**X**	**X**		**X**
Rainbow trout	*Oncorhynchus mykiss*	**X**		**X**	**X**			
Sculpin [b]	*Cottus* sp.	**X**	x	**X**	**X**	**X**	**X**	**X**
Ninespine stickleback	*Pungitius pungitius*	x	x	**X**				
Threespine stickleback	*Gasterosteus aculeatus*						**X**	
Longnose sucker	*Catostomus catostomus*		**X**					

Notes:

a. No fish were observed during fish surveys conducted in the Isolated Watershed Group.

b. Identified to genus, may include slimy sculpin and coastrange sculpin.

X = Species observed at primary survey site.

x = Species only observed at support survey site.

PHOTOGRAPHS

PHOTO 15.3-1: Habitat surveys to document the types and quality of aquatic habitats present in the transportation corridor study area were conducted. Habitat unit measurements were collected with a 165-foot (50-meter) Kevlar tape (A) and a stadia rod (B).

PHOTO 15.3-2: To determine fish presence in the transportation corridor study area, snorkel surveys (A and B) and electrofishing surveys (D) were conducted. Fish captured via electrofishing were measured to fork length (C).

Location

Site: MP_23.2 **Field Latitude:** 59.83888 **Subwatershed:** Negro Lake trib
Watershed: Negro Lake **Field Longitude:** -154.77419 **Stream:** Negro Lake trib

Site MP_23.5 was dry when visited on 09/08/08; no data was collected.

Figure 1. Site MP_23.2, taken on 09/08/08.

Transportation Corridor Site Survey Data

Location

Site: D 22.933 **Field Latitude:** 59.83078 **Subwatershed:** unnamed lake
Watershed: unnamed lake **Field Longitude:** -154.76723 **Stream:** unnamed lake trib

Site D 22.933 was dry when visited on 07/07/04; no data was collected. When the site was revisited and surveyed on 10/01/07, flowing water was present. The stream was associated with seasonally inundated wetlands and lacked a clearly defined channel. During senior review and Level 3 QC, this site was classified as a flowing wetland.

Transportation Corridor Site Survey Data

Location

Site: D 24.68 **Field Latitude:** 59.80577 **Subwatershed:** Roadhouse Ck. trib
Watershed: Roadhouse Ck. **Field Longitude:** -154.76863 **Stream:** secondary Roadhouse Ck. trib
When visited on 07/07/04, Site D 24.68 was mostly dry with tiny trickles of water; no data was collected. The site was revisited and surveyed on 10/02/07, when flowing water was present at the surveyed site, but the stream had only subsurface flow upstream and downstream of Site D 24.68.

Figure 1. Site D 24.68, taken on 10/02/07.

Channel (surveyed 10/02/07)

Gradient (%): 0.75

Transportation Corridor Site Survey Data

Location

Site: F 25.86 **Field Latitude:** 59.80136 **Subwatershed:** Eagle Bay trib
Watershed: Eagle Bay trib **Field Longitude:** -154.72307 **Stream:** secondary Eagle Bay trib
Site F 25.86 was dry and lacked a defined stream channel when visited on 08/15/04 and 10/01/07; no data was collected. This area appears to be a wetland.

Figure 1. Site F 25.86, taken on 10/02/07.

Transportation Corridor Site Survey Data

Location

Site: F 27.78 **Field Latitude:** 59.80238 **Subwatershed:** Eagle Bay trib
Watershed: Eagle Bay trib **Field Longitude:** -154.67198 **Stream:** tertiary Eagle Bay trib

No photo of Site F 27.78 was available from the 08/15/04 survey; the stream was revisited for photo documentation on 10/02/07.

Figure 1. Site F 27.78, taken on 10/02/07.

Channel (surveyed 08/15/04)

15.4 Macroinvertebrates and Periphyton—Transportation Corridor Study Area

15.4.1 Introduction

The macroinvertebrate and periphyton studies in the transportation-corridor study area are part of the overall program of baseline investigations used to describe the current aquatic conditions in the study area. Section 15.2.1 describes what macroinvertebrates and periphyton are, as well as their importance to the environmental baseline studies. The sections below describe the methods for and findings of the macroinvertebrate and periphyton field studies conducted during the summers of 2004 and 2005 in the transportation-corridor study area. Two years of characterization data have been collected; however, for some data sets (e.g., ADF&G methods, chlorophyll-*a*), only one year of baseline data exists because of a change in the sampling methods between 2004 and 2005 (see Section 15.4.4).

15.4.2 Study Objectives

The objectives for the macroinvertebrate and periphyton field and laboratory program were to characterize diversity, abundance, and density of macroinvertebrates and periphyton within freshwater habitats in the transportation corridor study area.

15.4.3 Study Area

The transportation-corridor study area for macroinvertebrates and periphyton in the Bristol Bay drainages consisted of three stream-sampling sites (Figure 15.4-1; Table 15.4-1). These sites were mostly on unnamed streams that were, for reporting purposes, named Bear Den Creek, Red Creek, and Ursa 100B. (The transportation-corridor study area extends eastward beyond the Bristol Bay drainages into the Cook Inlet drainages. Section 40.2 in Chapter 40 describes the macroinvertebrate and periphyton studies in the Cook Inlet drainages study area. Hydrology, water quality, and fish also were studied at all macroinvertebrate and periphyton sites.

15.4.4 Scope of Work

Information review began in spring 2004 and field work was conducted during the 2004 and 2005 field seasons. Sample and data analysis was conducted throughout that time and continued into 2006. The macroinvertebrate and periphyton studies were conducted in accordance with the applicable procedures described in Chapter 11 of the consolidated study program for the environmental baseline studies (see Appendix E of this environmental baseline document). Overall QA/QC for the baseline studies are described in the annual quality assurance project plans (see Appendix G of this environmental baseline document).

The 2004 sampling program in the transportation-corridor study area consisted of the following tasks:

- Macroinvertebrate sampling using the ASCI method. One composite sample was collected at each site.

- Macroinvertebrate sampling using the drift-net method. One composite sample was collected at each site.
- Periphyton sampling using the modified RBP method. One composite diatom sample sample was collected at each site.
- Ambient water-quality measurements. One measurement of each parameter was recorded at each site.

Preliminary analysis of 2004 data and discussions on proposed data use and conditions in the study area resulted in a decision to modify the sampling program for 2005. The 2005 sampling program consisted of the following tasks:

- Macroinvertebrate sampling using the ASCI method. One composite sample was collected at each site.
- Macroinvertebrate sampling using the Surber sampler semi-quantitative method. Five samples were collected at each site.
- Periphyton sampling using the ADF&G method. Ten chlorophyll a samples were collected at each site.
- Ambient water-quality measurements. One measurement of each parameter was recorded at each site.

15.4.5 Macroinvertebrate Methods

In 2004, sampling for macroinvertebrates in the transportation-corridor study area occurred during one event on August 17 and 18. In 2005, sampling occurred on June 11 and 12. Sampling was conducted at the same three sites in both years (Figure 15.4-1). Methods for collection and processing of macroinvertebrates and for analyses of the data were the same as those used for the mine study area in 2004 and 2005 (Section 15.2.5). A duplicate sample was collected at one sample site (10 percent) for QA/QC purposes.

15.4.6 Periphyton Methods

Sampling for periphyton in the transportation-corridor study area was concurrent with sampling for macroinvertebrates (Section 15.4.5). Methods for collection and processing of periphyton samples and analyses of the data were the same as those used in the mine study area in 2004 and 2005 (Section 15.2.6). A duplicate sample was collected at one site (10 percent) for QA/QC purposes.

15.4.7 Results and Discussion

15.4.7.1 Macroinvertebrates

During the 2004 and 2005 sampling events six composite drift samples, nine composite ASCI samples and 15 Surber samples were collected in the transportation-corridor study area. Macroinvertebrates were collected successfully from all sites except Red Creek in 2004; the ASCI sample collected at Red Creek in August 2004 was lost because of a broken sample bottle. Two hundred thirty five macroinvertebrate

taxa, including 64 Chironomidae taxa, have been identified in the Bristol Bay drainages study area (which includes both the mine [Section 15.2] and the transportation-corridor study areas). Tables 15.2-2 and 15.2-3 list all the taxa identified. Three of the non-Chironomidae macroinvertebrate taxa and three of the Chironomidae taxa were identified only in transportation-corridor study area samples. Of the non-Chironomidae taxa identified only in the transportation-corridor study area samples, one taxon was identified only in 2004. One of the Chironomidae taxa identified only in transportation-corridor study area samples was identified only in samples collected in 2004, and two were identified only in samples from 2005. Differences in numbers of taxa collected in 2004 compared to 2005 could be the result of changes in the sampling program. However, the difference in taxa richness between 2004 and 2005 at transportation-corridor study area sites was not as great as the difference in the mine study area. The same number of sites was sampled in the transportation-corridor study area in both years (three total), which could account for the smaller difference in taxa richness, as compared to the mine study area where the number of sites was reduced in 2005 from 20 to eight (offering less opportunity for collecting organisms).

Metrics that describe the macroinvertebrate population at each sample site were calculated as described in Section 15.2.5.3. The results are shown by year and sampling method in Tables 15.4-2 through 15.4-5. Figures 15.4-2 and 15.4-3 illustrate taxa richness at transportation-corridor study area sites in 2004 and 2005, respectively. Slightly more taxa per site were collected using the ASCI method in 2004 than in 2005, indicating possible interannual variability. The number of taxa collected in 2005 from riffle/cobble areas by Surber sampler was generally less than the in ASCI samples, which were collected in more diverse habitats. Habitat data collected at the time of sampling indicated that riffle/cobble areas comprised a large component of the habitats in streams along the transportation-corridor study area. At sites sampled in 2005, the proportion of riffle/cobble habitat in each stream reach ranged from 70 to 85 percent. The non-cobble habitats sampled (using ASCI methods) in the transportation-corridor study area appear to have higher taxa richness than those sampled in the mine study area, where the difference between ASCI and Surber samples was smaller.

Unlike the mine study area, Diptera, including the Family Chironomidae, was not the clearly dominant taxa at sampling sites in the transportation-corridor study area (Figures 15.4-4 and 15.4-5). In 2005, Diptera comprised a higher percentage than EPT in ASCI samples from all the sites, while EPT taxa comprised a higher percentage than Diptera in Surber samples from all the sites. This may indicate that there were more Diptera taxa in the varied habitats sampled using ASCI methods.

Measurements of water-quality and habitat-quality parameters at each site (Tables 15.4-6 through 15.4-8) fall within ranges considered good to optimal for aquatic and riparian habitat (Major and Barbour, 2001). The concentration of DO was consistently high at all sites and supersaturation (DO higher than 100 percent) was found at some sites (see explanation in Section 15.2.7.1). Water temperature ranged from 5.5 to 13.2°C and was much lower in 2005 than in 2004 except at Ursa 100B (Tables 15.4-6 and 15.4-7). No statistical analyses were performed on water-quality and macroinvertebrate metric data because of limited data, and no trends were immediately obvious.

15.4.7.2 Periphyton

Periphyton was collected successfully from all three sites during the 2004 and 2005 sampling events. In 2004, 36 diatom genera and 188 species were found in the Bristol Bay drainages study area (Table 15.2-20). In 2005, periphyton samples were collected for analysis for chlorophyll-*a* concentration as a quantifiable measure of productivity (Table 15.4-9).

Among the three sites sampled in the transportation-corridor study area in 2004, periphyton taxa richness ranged from 13 to 22 (Table 15.4-9 and Figure 15.4-6) and percent dominant taxon ranged from 52 to 68 percent (Table 15.4-9). In 2005, chlorophyll-*a* concentrations were highest at Bear Den Creek and lowest at Ursa 100B (Table 15.4-9 and Figure 15.4-7). All three of these sites were largely dominated by Chironomidae (more than 60 percent), of which some genera feed heavily on periphyton. Statistical analysis of these results was not performed because of the limited data set.

15.4.8 Summary

Three sites were sampled in the transportation-corridor study area during the fall of 2004 and the spring of 2005. Methods for collection and analysis differed between 2004 and 2005 for both macroinvertebrates and periphyton. Sample sites selected varied in stream size and habitat. Aquatic habitat surveys indicate that the sample sites consisted largely of riffle/cobble habitat, which is the highest quality habitat for EPT taxa.

A range of macroinvertebrate and periphyton sample-collection methods was employed during the beginning stages of this project to determine which methods would work best in these systems. The variety of methods used contributes greatly to the robustness of the baseline data-collection. Slightly more taxa per site were collected using the ASCI method in 2004 than in 2005, indicating possible interannual variability. The number of taxa collected in 2005 from riffle/cobble areas by Surber sampler was generally less than the in ASCI samples, which were collected in more diverse habitats. The non-cobble habitats sampled (using ASCI methods) in the transportation-corridor study area appear to have higher taxa richness than those sampled in the mine study area, where the difference between ASCI and Surber samples was smaller.

Unlike the mine study area, Diptera was not the dominant taxa at sampling sites in the transportation-corridor study area. In 2005, Diptera comprised a higher percentage than EPT in ASCI samples from all the sites, while EPT taxa comprised a higher percentage than Diptera in Surber samples from all the sites. This may indicate that there were more Diptera taxa in the varied habitats sampled using ASCI methods.

Periphyton taxa richness and chlorophyll-*a* concentrations were both higher at Bear Den Creek than at the other two sites.

15.4.10 Glossary

Diatom—microscopic algae with cells that have two separate halves and walls made of silicon.

Macroinvertebrates—organisms with no backbone and that are large enough to be seen without the aid of a microscope.

Metrics—standards of measurement.

Periphyton—micro-algae that attaches to rocks or other solid surfaces.

Taxon (plural: taxa)—a taxonomic category or group, such as a phylum, order, family, genus, or species.

15.5 Zooplankton—Iliamna Lake

15.5.1 Introduction

An integrated study of water quality, mussel tissue, sediment, and zooplankton was conducted to characterize baseline conditions for Iliamna Lake. The Iliamna Lake study objectives, study area, scope of work, methods, and results are described in full in Appendix B of this environmental baseline document. A brief overview of the zooplankton portion of the Iliamna Lake study is presented below.

Zooplankton were sampled as part of the Iliamna Lake study because they are indicators of lake-system water quality and are a primary source of food for plankton-eating fish such as juvenile sockeye salmon. The data collected provide baseline information on conditions in the lake. Sampling sites for the Iliamna Lake study were selected based on their proximity to the transportation corridor study area and populated villages. Five sites (Pile Bay, Knutson Bay, Northeast Bay, Roadhouse Bay, and the mouth of Upper Talarik Creek; see Figure 15.4-8) were sampled monthly for zooplankton in May through October 2005 and 2007, except sampling did not take place at the mouth of Upper Talarik Creek in September 2005 because of weather conditions.

15.5.2 Summary of Results and Discussion

In addition to zooplankton taxa in the protozoa group, six zooplankton taxa in the animalia group were identified in the Iliamna Lake samples: Copepoda, Rotifera, Cladocera, Ostracoda, Laevicaudata, and Anostraca. Zooplankton taxa richness at the five Iliamna Lake study sites was similar to taxa richness documented in standard literature (Wetzel, 2001), as well as in previous studies of Iliamna Lake and other lakes in the region (Sweetman, 2001; Lenarz, 1966).

In both 2005 and in 2007, copepods and rotifers were more abundant than the other zooplankton taxa during all months in the season. In 2005, copepods dominated the sample composition in May and June, but were replaced by rotifers later in the summer and fall months. In 2007, however, copepods were the dominant taxa during most of the sampling months, and relative abundance generally increased throughout the season from May to October.

In both years, cladocerans were absent or were found in minimal numbers early in the season (May and June), but increased in numbers later in the summer and fall. Although cladocerans were generally a small percentage of the overall zooplankton community, this taxa was more prevalent at Knutson Bay than at other locations. Cladocerans made up over 50 percent of the taxa composition at Knutson Bay in July and August of 2005 and in August of 2007. Pile Bay had the overall lowest population of cladocera of the sites. With the exception of August 2007, cladocerans at Pile Bay never comprised more than 10 percent of the taxa found at the sampling sites. Ostracoda, Anostraca, and Laevicaudata were seldom found and made up less than one percent of the overall population of zooplankton from all sampling events at all sites.

Appendix B presents a more integrated analysis of the water quality, mussel tissue, sediment, and zooplankton sampling methodologies and results.

15.5.4 Glossary

Taxon (plural: taxa)—a taxonomic category or group, such as a phylum, order, family, genus, or species.

Zooplankton—small animals without backbones, mainly crustaceans and fish larvae, that float or drift in salt or fresh waters.
